A Framework for Evaluation of Machine Reading Comprehension
Gold Standards

Abstract

Machine Reading Comprehension (MRC) is the task of answering a question over a paragraph of text. While neural MRC systems gain popularity and achieve noticeable performance, issues are being raised with the methodology used to establish their performance, particularly concerning the data design of gold standards that are used to evaluate them. There is but a limited understanding of the challenges present in this data, which makes it hard to draw comparisons and formulate reliable hypotheses. As a first step towards alleviating the problem, this paper proposes a unifying framework to systematically investigate the present linguistic features, required reasoning and background knowledge and factual correctness on one hand, and the presence of lexical cues as a lower bound for the requirement of understanding on the other hand. We propose a qualitative annotation schema for the first and a set of approximative metrics for the latter. In a first application of the framework, we analyse modern MRC gold standards and present our findings: the absence of features that contribute towards lexical ambiguity, the varying factual correctness of the expected answers and the presence of lexical cues, all of which potentially lower the reading comprehension complexity and quality of the evaluation data.

Keywords: Machine Reading Comprehension, Question Answering, Evaluation Methodology, Annotation Schema

1. Introduction

There is a recent spark of interest in the task of Question Answering (QA) over unstructured textual data, also referred to as Machine Reading Comprehension (MRC). This is mostly due to wide-spread success of advances in various facets of deep learning related research, such as novel architectures (Vaswani et al., 2017) Sukhbaatar et al., 2015 that allow for efficient optimisation of neural networks consisting of multiple layers, hardware designed for deep learning purpose[1] and software frameworks (Abadi et al., 2016) Paszke et al., 2017 that allow efficient development and testing of novel approaches. These factors enable researchers to produce models that are pre-trained on large scale corpora and provide contextualised word representations (Peters et al., 2018) that are shown to be a vital component towards solutions for a variety of natural language understanding tasks, including MRC (Devlin et al., 2019).

Another important factor that led to the recent success in MRC-related tasks is the widespread availability of various large datasets, e.g., SQuAD (Rajpurkar et al., 2016), that provide sufficient examples for optimising statistical models. The combination of these factors yields notable results, even surpassing human performance (Lan et al., 2020).

MRC is a generic task format that can be used for various natural language understanding capabilities (Gardner et al., 2019). Therefore it is crucially important to establish a rigorous evaluation methodology in order to be able to draw reliable conclusions from conducted experiments. While increasing effort is put into the evaluation of novel architectures, such as keeping the evaluation data from public access to prevent unintentional overfitting to test data, performing ablation and error studies and introducing novel metrics (Dodge et al., 2019), surprisingly little is done to establish the quality of the data itself. Additionally, recent research arrived at worrisome findings: the data of those gold standards, which is usually gathered involving a crowd-sourcing step, suffers from flaws in design (Chen and Durrett, 2019a) or contains overly specific keywords (Jia and Liang, 2017). Furthermore, these gold standards contain “annotation artefacts”, cues that lead models into focusing on superficial aspects of text, such as lexical overlap and word order, instead of actual language understanding (McCoy et al., 2019) Gururangan et al., 2018). These weaknesses cast some doubt on whether the data can reliably evaluate the reading comprehension performance of the models they evaluate, i.e. if the models are indeed being assessed for their capability to read.

Figure 1 shows an example from HOTPOTQA.

---

1 https://cloud.google.com/tpu/
An evaluation methodology is vital to the fine-grained understanding of challenges associated with a single gold standard, in order to understand in greater detail which capabilities of MRC models it evaluates. More importantly, it allows to draw comparisons between multiple gold standards and between the results of respective state-of-the-art models that are evaluated on them. In this work, we take a step back and propose a framework to systematically analyse MRC evaluation data, typically a set of questions and expected answers to be derived from accompanying passages. Concretely, we introduce a methodology to categorise the linguistic complexity of the textual data and the reasoning and potential external knowledge required to obtain the expected answer. Additionally, we propose to take a closer look at the factual correctness of the expected answers, a quality dimension that appears under-explored in literature.

We demonstrate the usefulness of the proposed framework by applying it to precisely describe and compare six contemporary MRC datasets. Our findings reveal concerns about their factual correctness, the presence of lexical cues that simplify the task of reading comprehension and the lack of semantic altering grammatical modifiers. We release the raw data comprised of 300 paragraphs, questions and answers richly annotated under the proposed framework as a resource for researchers developing natural language understanding models and datasets to utilise further.

To the best of our knowledge this is the first attempt to introduce a common evaluation methodology for MRC gold standards and the first across-the-board qualitative evaluation of MRC datasets with respect to the proposed categories.

2. Framework for MRC Gold Standard Analysis

2.1. Problem definition

We define the task of machine reading comprehension, the target application of the proposed methodology as follows: Given a paragraph $P$ that consists of tokens (words) $p_1, \ldots, p_n$, and a question $Q$ that consists of tokens $q_1, \ldots, q_m$, the goal is to retrieve an answer $A$ with tokens $a_1, \ldots, a_{|A|}$. $A$ is commonly constrained to be one of the following cases (Liu et al., 2019b), illustrated in Figure 2:

- **Multiple choice**, where the goal is to predict $A$ from a given set of choices $\mathcal{A}$.
- **Cloze-style**, where $S$ is a sentence, and $A$ and $Q$ are obtained by removing a sequence of words such that $Q = S - A$. The task is to fill in the resulting gap in $Q$ with the expected answer $A$ to form $S$.
- **Span**, where is a continuous subsequence of tokens from the paragraph ($A \subseteq P$). Flavours include multiple spans as the correct answer or $A \subseteq Q$.

![Figure 2: Typical formulations of the MRC task](image)

- **Free form**, where $A$ is an unconstrained natural language string.

A gold standard $G$ is composed of $m$ entries $(Q_i, A_i, P_i)_{i \in \{1, \ldots, m\}}$. The performance of an approach is established by comparing its answer predictions $A_i^*$ on the given input $(Q_i, P_i)$ (and $A_i$ for the multiple choice setting) against the expected answer $A_i$ for all $i \in \{1, \ldots, m\}$ under a performance metric. Typical performance metrics are exact match (EM) or accuracy, i.e. the percentage of exactly predicted answers, and the $F1$ score – the harmonic mean between the precision and the recall of the predicted tokens compared to expected answer tokens. The overall F1 score can either be computed by averaging the F1 scores for every instance or by first averaging the precision and recall and then computing the F1 score from those averages (macro F1). Free-text answers, meanwhile, are evaluated by means of text generation and summarisation metrics such as BLEU (Papineni et al., 2001) or ROUGE-L (Lin, 2004).

2.2. Dimensions of Interest

In this section we describe a methodology to categorise gold standards according to linguistic complexity, required reasoning and background knowledge, and their factual correctness. Specifically, we use those dimensions as high-level categories of a qualitative annotation schema for annotating question, expected answer and the corresponding context. We further enrich the qualitative annotations by a metric based on lexical cues in order to approximate a lower bound for the complexity of the reading comprehen-
We differentiate between Problem setting that gold standard data. We are able to make observations about the challenges present in annotating them, we obtain measurable results and thus are able to draw conclusions about the correctness of answers produced by a model that is evaluated on partially incorrect data.

One way by which developers of modern crowd-sourced gold standards ensure quality is by having the same entry annotated by multiple workers (Trischler et al., 2017) and keeping only those with high agreement. We investigate whether this method is enough to establish a sound ground truth answer that is unambiguously correct. Concretely we annotate an answer as Debatable when the passage features multiple plausible answers, when multiple expected answers contradict each other, or an answer is not specific enough with respect to the question and a more specific answer is present. We annotate an answer as Wrong when it is factually wrong and a correct answer is present in the context.

Required Reasoning It is important to understand what types of reasoning the benchmark evaluates, in order to be able to accredit various reasoning capabilities to the models it evaluates. Our proposed reasoning categories are inspired by those found in scientific question answering literature (Jansen et al., 2016; Boratko et al., 2018), as research in this area focuses on understanding the required reasoning capabilities. We include reasoning about the Temporal succession of events, Spatial reasoning about directions and environment, and Causal reasoning about the cause-effect relationship between events. We further annotate (multiple-choice) answers that can only be answered By Exclusion of every other alternative.

We further extend the reasoning categories by operational logic, similar to those required in semantic parsing tasks (Berant et al., 2013), as solving those tasks typically requires “multi-hop” reasoning (Yang et al., 2018; Welbl et al., 2018). When an answer can only be obtained by combining information from different sentences joined by mentioning a common entity, concept, date, fact or event (from here on called entity), we annotate it as Bridge. We further annotate the cases, when the answer is a concrete entity that satisfies a Constraint specified in the question, when it is required to draw a Comparison of multiple entities’ properties or when the expected answer is an Intersection of their properties (e.g. “What do Person A and Person B have in common?”).

We are interested in the linguistic reasoning capabilities probed by a gold standard, therefore we include the appropriate category used by Wang et al. (2019). Specifically, we annotate occurrences that require understanding of Negation, Quantifiers (such as “every”, “some”, or “all”), Conditional (“if … then”) statements and the logical implications of Con-/Disjunction (i.e. “and” and “or”) in order to derive the expected answer.

Finally, we investigate whether arithmetic reasoning re-

Figure 3: The hierarchy of categories in our proposed annotation framework. Abstract higher-level categories are presented in bold while actual annotation features are shown in italics.
requirements emerge in MRC gold standards as this can probe for reasoning that is not evaluated by simple answer retrieval (Dua et al., 2019). To this end, we annotate the presence of **Addition** and **Subtraction**, answers that require **Ordering** of numerical values, **Counting** and **Other** occurrences of simple mathematical operations.

An example can exhibit multiple forms of reasoning. Notably, we do not annotate any of the categories mentioned above if the expected answer is directly stated in the passage. For example, if the question asks “How many total points were scored in the game?” and the passage contains a sentence similar to “The total score of the game was 51 points”, it does not require any reasoning, in which case we annotate it as **Retrieval**.

**Knowledge** Worthwhile knowing is whether the information presented in the context is sufficient to answer the question, as there is an increase of benchmarks deliberately designed to probe a model’s reliance on some sort of background knowledge (Storks et al., 2019). We seek to categorise the type of knowledge required. Similar to Wang et al. (2019), on the one hand we annotate the reliance on factual knowledge, that is (Geo)political/Legal, Cultural/Historic, Technical/Scientific and Other Domain Specific knowledge about the world that can be expressed as a set of facts. On the other hand, we denote Intuitive knowledge requirements, which is challenging to express as a set of facts, such as the knowledge that a parenthetic numerical expression next to a person’s name in a biography usually denotes his life span.

**Linguistic Complexity** Another dimension of interest is the evaluation of various linguistic capabilities of MRC models (Goldberg, 2019; Liu et al., 2019a; Tenney et al., 2019). We aim to establish which linguistic phenomena are probed by gold standards and to which degree. To that end, we draw inspiration from the annotation schema used by Wang et al. (2019), and adapt it around lexical semantics and syntax.

More specifically, we annotate features that introduce variance between the supporting facts and the question. With regard to lexical semantics, we focus on the use of redundant words that do not alter the meaning of a sentence for the task of retrieving the expected answer (Redundancy), requirements on the understanding of words’ semantic fields (Lexical Entailment) and the use of **Synonyms and Paraphrases** with respect to the question wording. Furthermore we annotate cases where supporting facts contain **Abbreviations** of concepts introduced in the question (and vice versa) and when a **Dative** case substitutes the use of a preposition (e.g. “I bought her a gift” vs “I bought a gift for her”). Regarding syntax, we annotate changes from passive to active **Voice**, the substitution of a **Genitive** case with a preposition (e.g. “of”) and changes from nominal to verbal style and vice versa (**Nominalisation**).

We recognise features that add ambiguity to the supporting facts, for example when information is only expressed implicitly by using an Ellipsis. As opposed to redundant words, we annotate **Restrictivity** and **Factivity** modifiers, words and phrases whose presence does change the meaning of a sentence with regard to the expected answer, and occurrences of intra- or inter-sentence **Coreference** in supporting facts (that is relevant to the question). Lastly, we mark ambiguous syntactic features, when their resolution is required in order to obtain the answer. Concretely, we mark argument collection with con- and disjunctions (**Listing**) and ambiguous **Prepositions**, **Coordination Scope** and **Relative clauses/Adverbial phrases/Appositions**.

**Complexity** Finally, we want to approximate the presence of lexical cues that might simplify the reading required in order to arrive at the answer. Quantifying this allows for more reliable statements about and comparison of the complexity of gold standards, particularly regarding the evaluation of comprehension that goes beyond simple lexical matching. We propose the use of coarse metrics based on lexical overlap between question and context sentences. Intuitively, we aim to quantify how much supporting facts “stand out” from their surrounding passage context. This can be used as proxy for the capability to retrieve the answer (Chen and Durrett, 2019a). Specifically, we measure (i) the number of words jointly occurring in a question and a sentence, (ii) the length of the longest n-gram shared by question and sentence and (iii) whether a word or n-gram from the question uniquely appears in a sentence.

The resulting taxonomy of the framework is shown in Figure 3. The full catalogue of features, their description, detailed annotation guideline as well as illustrating examples can be found in Appendix A.

3. Application of the Framework

3.1. Candidate Datasets

We select contemporary MRC benchmarks to represent all four commonly used problem definitions (Liu et al., 2019b). In selecting relevant datasets, we do not consider those that are considered “solved”, i.e. where the state of the art performance surpasses human performance, as is the case with SQUAD (Rajpurkar et al., 2018) and RACE (Lan et al., 2020). Concretely, we selected gold standards that fit our problem definition and were published in the years 2016 to 2019, have at least (2019 – publication year) × 20 citations, and bucket them according to the answer selection styles as described in Section 2.1. We randomly draw one from each bucket and add two randomly drawn datasets from the candidate pool. This leaves us with the datasets described in Table 1. For a more detailed description, we refer to Appendix C.

3.2. Annotation Task

We randomly select 50 distinct question, answer and passage triples from the publicly available development sets of the described datasets. Training, development and the (hidden) test set are drawn from the same distribution defined by the data collection method of the respective dataset. For those collections that contain multiple questions over a single passage, we ensure that we are sampling unique paragraphs in order to increase the variety of investigated texts. The samples were annotated by the first author of this paper, using the proposed schema. In order to validate our findings, we further take 20% of the annotated samples and present them to a second annotator (second author). Since
at its core, the annotation is a multi-label task, we report the inter-annotator agreement by computing the (micro-averaged) F1 score, where we treat the first annotator’s labels as gold. Table 2 reports the agreement scores, the overall (micro) average F1 score of the annotations is 0.82, which means that on average, more than two thirds of the overall annotated labels were agreed on by both annotators. We deem this satisfactory, given the complexity of the annotation schema.

### 3.3. Qualitative Analysis

We present a concise view of the annotation results in Figure 4. The full annotation results can be found in Appendix B. We centre our discussion around the following main points:

**Linguistic Features** As observed in Figure 4a, the gold standards feature a high degree of Redundancy, peaking at 76% of the annotated HOTPOTQA samples and synonyms and paraphrases (labelled Synonym), with RECoRD samples containing 58% of them, likely to be attributed to the elaborating type of discourse of the dataset sources (encyclopedia and newswire). This is, however, not surprising, as it is fairly well understood in the literature that current state-of-the-art models perform well on distinguishing relevant words and phrases from redundant ones (Seo et al., 2017). Additionally, the representational capability of synonym relationships of word embeddings has been investigated and is well known (Chen et al., 2013). Finally, we observe the presence of syntactic features, such as ambiguous relative clauses, appositions and adversarial phrases, (RelAdvApp 40% in HOTPOTQA and ReCoRd) and those introducing variance, concretely switching between verbal and nominal styles (e.g. Nominalisation 10% in HOTPOTQA) and from passive to active voice (Voice, 8% in HOTPOTQA).

Syntactic features contributing to variety and ambiguity that we did not observe in our samples are the exploitation of verb symmetry, the use of dative and genitive cases or ambiguous prepositions and coordination scope (respectively Symmetry, Dative, Genitive, Prepositions, Scope). Therefore we cannot establish whether models are capable of dealing with those features by evaluating them on those gold standards.

**Factual Correctness** We identify three common sources that surface in different problems regarding an answer’s factual correctness, as reported in Figure 4c and illustrate their instantiations in Table 3:

- **Design Constraints:** Choosing the task design and the
- **Factual Constraints:** When a question requires a factual answer,
- **Choice Constraints:** When a question allows for multiple correct answers.

Table 3: Most frequently occurring factually wrong and debatable categories with an instantiating example. Percentages are relative to the number of all examples annotated as Wrong respectively Debatable across all six gold standards.

**https://github.com/schlevik/dataset-analysis**
data collection method introduces some constraints that lead to factually debatable examples. For example, a span might have been arbitrarily selected from multiple spans that potentially answer a question, but only a single continuous answer span per question is allowed by design, as observed in the NEWSQA and MSMARCO samples (32% and 34% examples annotated as Debatable with 16% and 53% thereof exhibiting arbitrary selection, respectively). Sometimes, when additional passages are added after the annotation step, they can by chance contain passages that answer the question more precisely than the original span, as seen in HOTPOTQA (16% Debatable samples, 25% of them due to arbitrary selection). In the case of MULTIRC it appears to be inconsistent, whether multiple correct answer choices are expected to be correct in isolation or in conjunction (28% Debatable with 29% of them exhibiting this problem).

This might provide an explanation to its relatively weak human baseline performance of 84% F1 score (Khashabi et al., 2018).

- **Weak Quality assurance:** When the (typically crowdsourced) annotations are not appropriately validated, incorrect examples will find their way into the gold standards. This typically results in factually wrong expected answers (i.e. when a more correct answer is present in the context) or a question is expected to be Unanswerable, but is actually answerable from the provided context. The latter is observed in MSMARCO (83% of examples annotated as Wrong) and NEWSQA, where 60% of the examples annotated as Wrong are Unanswerable with an answer present.

- **Arbitrary Precision:** There appears to be no clear guideline on how precise the answer is expected to be, when the passage expresses the answer in vary-
Semantics-altering grammatical modifiers  We took interest in whether any of the benchmarks contain what we call *distracting lexical features* (or distractors): grammatical modifiers that alter the semantics of a sentence for the final task of answering the given question while preserving a similar lexical form. An example of such features are cues for (double) Negation (e.g., “no”, “not”), which when introduced in a sentence, reverse its meaning. Other examples include modifiers denoting *Restrictivity, Factivity* and *Reasoning* (such as *Monotonicity* and *Conditional* cues). Examples of question-answer pairs containing a distractor are shown in Table 5. We posit that the presence of such distractors would allow for evaluating reading comprehension beyond potential simple word matching. However, we observe no presence of such features in the benchmarks (beyond Negation in DROP, RECoRD and HOTPOTQA, with 4%, 4% and 2% respectively). This results in gold standards that clearly express the evidence required to obtain the answer, lacking more challenging, i.e., distracting, sentences that can assess whether a model can truly understand meaning.

Other In the Figure 4c we observe that *Operational* and *Arithmetic* reasoning moderately (6% to 8% combined) appears “in the wild”, i.e., when not enforced by the data design as is the case with HOTPOTQA (80% Operations combined) or DROP (68% Arithmetic combined). *Causal* reasoning is (exclusively) present in MULTIRC (32%), whereas *Temporal* and *Spatial* reasoning requirements seem to not naturally emerge in gold standards. In RECoRD, a fraction of 38% questions can only be answered By Exclusion of every other candidate, due to the design choice of allowing questions where the required information to answer them is not fully expressed in the accompanying paragraph. Therefore, it is also a little surprising to observe that RECoRD requires external resources with regard to knowledge, as seen in Figure 4d MULTIRC requires technical or more precisely basic scientific knowledge (6% Technical/Scientific), as a portion of paragraphs is extracted from elementary school science textbooks (Khashabi et al., 2018). Other benchmarks moderately probe for factual knowledge (0% to 4% across all categories), while *Intuitive* knowledge is required to derive answers in each gold standard.

It is also worth pointing out, as done in Figure 4b, that although MULTIRC and MSMARCO are not modelled as a span selection problem, their samples still contain 50% and 66% of answers that are directly taken from the context. DROP contains the biggest fraction of generated answers (60%), due to the requirement of arithmetic operations. To conclude our analysis, we observe similar distributions of linguistic features and reasoning patterns, except where there are constraints enforced by dataset design, annotation guidelines or source text choice. Furthermore, careful consideration of design choices (such as single-span answers) is required, to avoid impairing the factual correctness of datasets, as pure crowd-worker agreement seems not sufficient in multiple cases.

### 3.4 Quantitative Results

**Lexical overlap** We used the scores assigned by our proposed set of metrics (discussed in Section 2.2 Dimensions of Interest: Complexity) to predict the supporting facts in the gold standard samples (that we included in our manual annotation). Concretely, we used the following five features capturing lexical overlap: (i) the number of words occurring in sentence and question, (ii) the length of the longest n-gram shared by sentence and question, whether a (iii) unigram and (iv) bigram from the question is unique to a sentence, and (v) the sentence index, as input to a logistic regression classifier. We optimised on each sample leaving one example for evaluation. We compute the average Precision, Recall and F1 score within the 95% confidence interval of a linear classifier optimised on lexical features for the task of predicting supporting facts

Table 4: (Average) Precision, Recall and F1 score within the 95% confidence interval of a linear classifier optimised on lexical features for the task of predicting supporting facts

---

**Restrictivity Modification**

**Question:** What was the longest touchdown?  
**Expected Answer:** 42 yard TD.  
**Passage:** Brady scored a 42 yard TD. Brady almost scored a 50 yard TD.

**Factivity Altering**

**Question:** What are the details of the second plot on Alexander’s life?  
**(Wrong) Answer Choice:** Callisthenes of Olynthus was definitely involved.  
**Passage:** [...] His official historian, Callisthenes of Olynthus, was implicated in the plot; however, historians have yet to reach a consensus regarding this involvement.

**Conditional Statement**

**Question:** How many eggs did I buy?  
**Expected Answer:** 2.  
**Passage:** [...] I will buy 4 eggs, *if* the market sells milk. Otherwise, I will buy 2 [...] . The market had no milk.

Figure 5: Example of semantics altering lexical features
of semantics-altering grammatical modifiers discussed in the qualitative analysis section above. The classifier performs best on DROP (66% F1) and MULTIRC (40% F1), which means that lexical cues can considerably facilitate the search for the answer in those gold standards. On MULTIRC, [Yadav et al. (2019)] come to a similar conclusion, by using a more sophisticated approach based on overlap between question, sentence and answer choices. Surprisingly, the classifier is able to pick up a signal from supporting facts even on data that has been pruned against lexical overlap heuristics by populating the context with additional documents that have high overlap scores with the question. This results in significantly higher scores than when guessing randomly (HOTPOQA 26% F1, and MSMARCO 11% F1). We observe similar results in the case the length of the question leaves few candidates to compute overlap with 6.3 and 7.3 tokens on average for MSMARCO and NEWSQA (26% F1), compared to 16.9 tokens on average for the remaining four dataset samples. Finally, it is worth mentioning that although the queries in RECORd are explicitly independent from the passage, the linear classifier is still capable of achieving 34% F1 score in predicting the supporting facts. However, neural networks perform significantly better than our admittedly crude baseline (e.g. 66% F1 for supporting facts classification on HOTPOQA [Yang et al., 2018]), albeit utilising more training examples, and a richer sentence representation. This facts implies that those neural models are capable of solving more challenging problems than simple “text matching” as performed by the logistic regression baseline. However, they still circumvent actual reading comprehension as the respective gold standards are of limited suitability to evaluate this [Min et al., 2019; Jiang and Bansal, 2019]. This suggests an exciting future research direction, that is categorising the scale between text matching and reading comprehension more precisely and respectively positioning state-of-the-art models thereon.

4. Related Work

Although not as prominent as the research on novel architecture, there has been steady progress in critically investigating the data and evaluation aspects of NLP and machine learning in general and MRC in particular.

Adversarial Evaluation The authors of the ADDSENT algorithm [Jia and Liang, 2017] show that MRC models trained and evaluated on the SQUAD dataset pay too little attention to details that might change the semantics of a sentence, and propose a crowd-sourcing based method to generate adversary examples to exploit that weakness. This method was further adapted to be fully automated [Wang and Bansal, 2018] and applied to different gold standards [Jiang and Bansal, 2019]. Our proposed approach differs in that we aim to provide qualitative justifications for those quantitatively measured issues.

Sanity Baselines Another line of research establishes sane baselines to provide more meaningful context to the raw performance scores of evaluated models. When removing integral parts of the task formulation such as question, the textual passage or parts thereof (Kaushik and Lipton, 2018) or restricting model complexity by design in order to suppress some required form of reasoning (Chen and Durrett, 2019b), models are still able to perform comparably to the state-of-the-art. This raises concerns about the perceived benchmark complexity and is related to our work in a broader sense as one of our goals is to estimate the complexity of benchmarks.

5. Conclusion

In this paper, we introduce a novel framework to characterise machine reading comprehension gold standards. This framework has potential applications when comparing different gold standards, considering the design choices for a new gold standard and performing qualitative error analyses for a proposed approach. Furthermore we applied the framework to analyse popular state-of-the-art gold standards for machine reading comprehension: We reveal issues with their factual correctness, show the presence of lexical cues and we observe that semantics-altering grammatical modifiers are missing in all of the investigated gold standards. Studying how to introduce those modifiers into gold standards and observing whether state-of-the-art MRC models are capable of performing reading comprehension on text containing them, is a future research goal. A future line of research is to extend the framework to be able to identify the different types of exploitable cues such as question or entity typing and concrete overlap patterns. This will allow the framework to serve as an interpretable estimate of reading comprehension complexity of gold standards. Finally, investigating gold standards under this framework where MRC models outperform the human baseline (e.g. SQUAD) will contribute to a deeper understanding of the seemingly superb performance of deep learning approaches on them.

A Annotation Schema

Here, we describe our annotation schema in greater detail. We present the respective phenomenon, give a short description and present an example that illustrates the feature. Examples for categories that occur in the analysed samples are taken directly from observed data and therefore do not represent the views, beliefs or opinions of the authors. For those categories that were not annotated in the data we construct a minimal example.

Supporting Fact
We define and annotate “Supporting fact(s)” in line with contemporary literature as the (minimal set of) sentence(s) that is required in order to provide an answer to a given question. Other sources also call supporting facts “evidence”.

Answer Type
Span We mark an answer as span if the answer is a text span from the paragraph.

Question: Who was freed from collapsed roadway tunnel?

Passage: […] The quake collapsed a roadway tunnel, temporarily trapping about 50 construction workers. […]

Expected Answer: 50 construction workers.

Paraphrasing We annotate an answer as paraphrasing if the expected correct answer is a paraphrase of a textual span. This can include the usage of synonyms, altering the constituency structure or changing the voice or mode.

Question: What is the CIA known for?

Passage: […] The CIA has a reputation for agility […]

Expected Answer: CIA is known for agility.

Unanswerable We annotate an answer as unanswerable if the answer is not provided in the accompanying paragraph.

Question: average daily temperature in Beaufort, SC

Passage: The highest average temperature in Beaufort is June at 80.8 degrees. The coldest average temperature in Beaufort is February at 50 degrees […]

Expected Answer: 50 degrees.

Generated We annotate an answer as generated, if and only if it does not fall into the three previous categories. Note that neither answers that are conjunctions of previous categories (e.g. two passage spans concatenated with “and”) nor results of concatenating passage spans or restating the question in order to formulate a full sentence (i.e. enriching it with pronomina) are counted as generated answers.

Question: How many total points were scored in the game?

Passage: […] as time expired to shock the Colts 27-24.

Expected Answer: 51.

Quality
Debatable We annotate an answer as debatable, either if it cannot be deduced from the paragraph, if there are multiple plausible alternatives or if the answer is not specific enough. We add a note with the alternatives or a better suiting answer.

Question: what does carter say?

Passage: […] “From the time he began, […]” the former president […] said in a statement. “Jody was beside me in every decision I made […]”

Expected Answer: “Jody was beside me in every decision I made […]” (This is an arbitrary selection as more direct speech is attributed to Carter in the passage.)

Wrong We annotate an answer as wrong, if the answer is factually wrong. Further, we denote why the answer is wrong and what the correct answer should be.

Question: What is the cost of the project?

Passage: […] At issue is the […] platform, […] that has cost taxpayers $1.2 billion in earmarks since 2004. It is estimated to cost at least $2.9 billion more […]

Expected Answer: $2.9 Billion. (The overall cost is at least $4.1 Billion)

Linguistic Features
We annotate occurrences of the following linguistic features in the supporting facts. On a high-level, we differentiate between syntax and lexical semantics, as well as variety and ambiguity. Naturally, features that concern question and corresponding passage context tend to fall under the variety category, while features that relate to the passage only are typically associated with the ambiguity category.

Lexical Variety
Redundancy We annotate a span as redundant, if it does not alter the factuality of the sentence. In other words the answer to the question remains the same if the span is removed (and the sentence is still grammatically correct).

Question: When was the last time the author went to the cellars?

Passage: I had not, [if I remember rightly]Redundancy, been into [the cellars] since [my hasty search on]Redundancy the evening of the attack.
Lexical Entailment  We annotate occurrences, where it is required to navigate the semantic fields of words in order to derive the answer as lexical entailment. In other words we annotate cases, where the understanding of words’ hypernymy and hyponomy relationships is necessary to arrive at the expected answer.

Question: What [food items]LexEntailment are mentioned?
Passage: He couldn’t find anything to eat except for [pie]LexEntailment! Usually, Joey would eat [cereal]LexEntailment, [fruit]LexEntailment (a [pear]LexEntailment), or [oatmeal]LexEntailment for breakfast.

Dative  We annotate occurrences of variance in case of the object (i.e. from dative to using preposition) in the question and supporting facts.

Question: Who did Mary buy a gift for?
Passage: Mary bought Jane a gift.

Synonym and Paraphrase  We annotate cases, where the question wording uses synonyms or paraphrases of expressions that occur in the supporting facts.

Question: How many years longer is the life expectancy of [women]Synonym than [men]Synonym?
Passage: Life expectancy is [female]Synonym 75, [male]Synonym 72.

Abbreviation  We annotate cases where the correct resolution of an abbreviation is required, in order to arrive at the answer.

Question: How many [touchdowns]Abbreviation did the Giants score in the first half?
Paragraph: [...] with RB Brandon Jacobs getting a 6-yard and a 43-yard [TD]Abbreviation run [...]  

Symmetry, Collectivity and Core arguments  We annotate the argument variance for the same predicate in question and passage such as argument collection for symmetric verbs or the exploitation of ergative verbs.

Question: Who married John?
Passage: John and Mary married.

Syntactic Variety

Nominalisation  We annotate occurrences of the change in style from nominal to verbal (and vice versa) of verbs (nouns) occurring both in question and supporting facts.

Question: What show does [the host of]Nominalisation The 2011 Teen Choice Awards ceremony currently star on?

Genitives  We annotate cases where possession of an object is expressed by using the genitive form (“’s”) in question and differently (e.g. using the preposition “of”) in the supporting facts (and vice versa).

Question: Who used Mary’s computer?
Passage: John’s computer was broken, so he went to Mary’s office where he used the computer of Mary.

Voice  We annotate occurrences of the change in voice from active to passive (and vice versa) of verbs shared by question and supporting facts.

Question: Where does Mike Leach currently [coach at]Voice?
Passage: [The 2012 Washington State Cougars football team] was [coached]Voice by by first-year head coach Mike Leach [...]  

Lexical Ambiguity

Restrictivity  We annotate cases where restrictive modifiers need to be resolved in order to arrive at the expected answers. Restrictive modifiers – opposed to redundancy – are modifiers that change the meaning of a sentence by providing additional details.

Question: How many dogs are in the room?
Passage: There are 5 dogs in the room. Three of them are brown. All the [brown]Restrictivity dogs leave the room.

Factivity  We annotate cases where modifiers – such as verbs – change the factivity of a statement.

Question: When did it rain the last time?
Passage: Upon reading the news, I realise that it rained two days ago. I believe it rained yesterday.
Expected Answer: two days ago

Coreference  We annotate cases where intra- or inter-sentence coreference and anaphora need to be resolved in order to retrieve the expected answer.

Question: What is the name of the psychologist who is known as the originator of social learning theory?
Passage: Albert Bandura OC (born December 4, 1925) is a psychologist who is the David Starr Jordan Professor Emeritus of Social Science in Psychology at Stanford University. [...] He is known as the originator of social learning theory and the theoretical construct of self-efficacy, and is also responsible for the influential 1961 Bobo doll experiment.
**Ellipsis/Implicit** We annotate cases where required information is not explicitly expressed in the passage.

*Question:* How many years after producing Happy Days did Beckett produce Rockaby?

*Passage:* [Beckett] produced works […], including […], Happy Days [(1961)] Implicit, and Rockaby [(1981)] Implicit. *(The date in brackets indicates the publication date implicitly.)*

**Syntactic Ambiguity**

**Preposition** We annotate occurrences of ambiguous prepositions that might obscure the reasoning process if resolved incorrectly.

*Question:* What tool do you eat spaghetti with?

*Passage:* Let’s talk about forks. You use them to eat spaghetti with meatballs.

**Listing** We define listing as the case where multiple arguments belonging to the same predicate are collected with conjunctions or disjunctions (i.e. “and” or “or”). We annotate occurrences of listings where the resolution of such collections and mapping to the correct predicate is required in order to obtain the information required to answer the question.

*Passage:* [She is also known for her roles] Predicate [as White House aide Amanda Tanner in the first season of ABC’s ”Scandal”] Argument [and] Listing [as attorney Bonnie Winterbottom in ABC’s ”How to Get Away with Murder”] Argument.

**Coordination Scope** We annotate cases where the scope of a coordination may be interpreted differently and thus lead to a different answer than the expected one. *Question:* Where did I put the marbles?

*Passage:* I put the marbles in the box and the bowl on the table. Depending on the interpretation, the marbles were either put both in the box and in the bowl that was on the table, or the marbles were put in the box and the bowl was put on the table.

**Relative clause, adverbial phrase and apposition** We annotate cases that require the correct resolution of relative pronouns, adverbial phrases or appositions in order to answer a question correctly.

*Question:* José Saramago and Ivo Andrić were recipients of what award in Literature?

*Passage:* Ivo Andrić […] was a Yugoslav novelist, poet and short story writer [who] Relative won the Nobel Prize in Literature in 1961.

**Required Reasoning**

**Operational Reasoning**

We annotate occurrences of the arithmetic operations described below. Operational reasoning is a type of abstract reasoning, which means that we do not annotate passages that explicitly state the information required to answer the question, even if the question’s wording might indicate it. For example, we don’t regard the reasoning in the question “How many touchdowns did the Giants score in the first half?” as operational (counting) if the passage states “The Giants scored 2 touchdowns in the first half.”

**Bridge** We annotate cases where information to answer the question needs to be gathered from multiple supporting facts, “bridged” by commonly mentioned entities, concepts or events. This phenomenon is also known as “Multi-hop reasoning” in literature.

*Question:* What show does the host of The 2011 Teen Choice Awards ceremony currently star on?

*Passage:* […] The 2011 Teen Choice Awards ceremony, hosted by [Kaley Cuoco] Entity, aired live on August 7, 2011 at 8/7c on Fox. […] [Kaley Christine Cuoco] Entity is an American actress. Since 2007, she has starred as Penny on the CBS sitcom "The Big Bang Theory", for which she has received Satellite, Critics’ Choice, and People’s Choice Awards.

**Comparison** We annotate questions where entities, concepts or events need to be compared with regard to their properties in order to answer a question.

*Question:* What year was the alphabetically first writer of Fairytale of New York born?

*Passage:* “Fairytale of New York” is a song written by Jem Finer and Shane MacGowan […].

**Constraint Satisfaction** Similar to the Join category, we annotate instances that require the retrieval of entities, concepts or events which additionally satisfy a specified constraint.

*Question:* Which Australian singer-songwriter wrote Cold Hard Bitch?

*Passage:* ["Cold Hard Bitch"] was released in March 2004 and was written by band-members Chris Cester, Nic Cester, and Cameron Muncey. […] Nicholas John ”Nic” Cester is an Australian singer-songwriter and guitarist […].

**Intersection** Similar to the Comparison category, we annotate cases where properties of entities, concepts or events need need to be reduced to a minimal common set.

*Question:* José Saramago and Ivo Andrić were recipients of what award in Literature?

**Arithmetic Reasoning**

We annotate occurrences of the arithmetic operations described below. Similarly to operational reasoning, arithmetic reasoning is a type of abstract reasoning, so we annotate it analogously. An example for non-arithmetic reasoning is, if the question states “How many total points were scored in the game?” and the passage expresses the required information similarly to “There were a total of 51 points scored in the game.”
**Subtraction**  
*Question:* How many points were the Giants behind the Dolphins at the start of the 4th quarter?  
*Passage:* New York was down 17-10 behind two rushing touchdowns.

**Addition**  
*Question:* How many total points were scored in the game?  
*Passage:* [...] Kris Brown kicked the winning 48-yard field goal as time expired to shock the Colts 27-24.

**Ordering**  
We annotate questions with this category, if it requires the comparison of (at least) two numerical values (and potentially a selection based on this comparison) to produce the expected answer.  
*Question:* What happened second: Peace of Paris or appointed governor of Artois?  
*Passage:* He [...] retired from active military service when the war ended in 1763 with the Peace of Paris. He was appointed governor of Artois in 1765.

**Count**  
We annotate questions that require the explicit enumeration of events, concepts, facts or entities.  
*Question:* How many touchdowns did the Giants score in the first half?  
*Passage:* In the second quarter, the Giants took the lead with RB Brandon Jacobs getting a 6-yard and a 43-yard TD run [...].

**Other**  
We annotate any other arithmetic operation that does not fall into any of the above categories with this label.  
*Question:* How many points did the Ravens score on average?  
*Passage:* Baltimore managed to beat the Jets 10-9 on the 2010 opener [...]. The Ravens rebounded [...], beating Cleveland 24-17 in Week 3 and then Pittsburgh 17-14 in Week 4. [...] Next, the Ravens hosted Miami and won 26-10, breaking that teams 4-0 road streak.

**Linguistic Reasoning**

**Negations**  
We annotate cases where the information in the passage needs to be negated in order to conclude the correct answer.  
*Question:* How many percent are not Marriage couples living together?  
*Passage:* [...] 46.28% were Marriage living together. [...]

**Conjunctions and Disjunctions**  
We annotate occurrences, where in order to conclude the answer logical conjunction or disjunction needs to be resolved.  
*Question:* Is dad in the living room?  
*Passage:* Dad is either in the kitchen or in the living room.

**Conditionals**  
We annotate cases where the the expected answer is guarded by a condition. In order to arrive at the answer, the inspection whether the condition holds is required.  
*Question:* How many eggs did I buy?  
*Passage:* I am going to buy eggs. If you want some, too, I will buy 6, if not I will buy 3. You didn’t want any.

**Quantification**  
We annotate occurrences, where it is required to understand the concept of quantification (existential and universal) in order to determine the correct answer.  
*Question:* How many presents did Susan receive?  
*Passage:* On the day of the party, all five friends showed up. [Each friend] had a present for Susan.

**Other types of reasoning**

**Temporal**  
We annotate cases, where understanding about the succession is required in order to derive an answer. Similar to arithmetic and operational reasoning, we do not annotate questions where the required information is expressed explicitly in the passage.  
*Question:* Where is the ball?  
*Passage:* I take the ball. I go to the kitchen after going to the living room. I drop the ball. I go to the garden.

**Spatial**  
Similarly to temporal, we annotate cases where understanding about directions, environment and spatiality is required in order to arrive at the correct conclusion.  
*Question:* What is the 2010 population of the city 2.1 miles southwest of Marietta Air Force Station?  
*Passage:* [Marietta Air Force Station] is located 2.1 mi northeast of Smyrna, Georgia.

**Causal**  
We annotate occurrences where causal (i.e. cause-effect) reasoning between events, entities or concepts is required to correctly answer a question. We do not annotate questions as causal, if passages explicitly reveal the relationship in a “effect because cause” manner. For example we don’t annotate “Why do men have a hands off policy when it comes to black women’s hair?” as causal, even if the wording indicates it, because the corresponding passage immediately reveals the relationship by stating “Because women spend so much time and money on their hair, Rock says men are forced to adopt a hands-off policy.”.  
*Question:* Why did Sam stop Mom from making four sandwich?  
*Passage:* [...] There are three of us, so we need three sandwiches. [...]

We annotate occurrences (in the multiple-choice setting) where there is not enough information present to directly determine the expected answer, and the expected answer can only be assumed by excluding alternatives.

**Question:** Calls for a withdrawal of investment in Israel have also intensified because of its continuing occupation of @placeholder territories – something which is illegal under international law.

**Answer Choices** Benjamin Netanyahu, Paris, [Palestinian]Answer, French, Israeli, Partner’s, West Bank, Telecoms, Orange

---

**Information Retrieval** We collect cases that don’t fall under any of the described categories and where the answer can be directly retrieved from the passage under this category.

**Question:** Officers were fatally shot where?

**Passage:** The Lakewood police officers [...] were fatally shot November 29 [in a coffee shop near Lakewood]Answer.

---

**Knowledge**

We recognise passages that do not contain the required information in order to answer a question as expected. These non self sufficient passages require models to incorporate some form of external knowledge. We distinguish between factual and common sense knowledge.

---

**Factual**

We annotate the dependence on factual knowledge – knowledge that can clearly be stated as a set facts – from the domains listed below.

- **Cultural/Historic**
  **Question:** What are the details of the second plot on Alexander’s life in the Central Asian campaign?
  **Passage:** Later, in the Central Asian campaign, a second plot against his life was revealed, this one instigated by his own royal pages. His official historian, Callisthenes of Olynthus, was implicated in the plot; however, historians have yet to reach a consensus regarding this involvement.
  **Expected Answer:** Unsuccessful

- **Geographical/Political**
  **Question:** Calls for a withdrawal of investment in Israel have also intensified because of its continuing occupation of @placeholder territories – something which is illegal under international law.
  **Passage:** […] But Israel lashed out at the decision, which appeared to be related to Partner’s operations in the occupied West Bank. […]
  **Expected Answer:** Palestinian

- **Legal**
  **Question:** […] in part due to @placeholder – the 1972 law that increased opportunities for women in high school and college athletics – and a series of court decisions.
  **Passage:** […] Title IX helped open opportunity to women too; Olympic hopeful Marlen Exparza one example. […]
  **Expected Answer:** Title IX

- **Technical/Scientific**
  **Question:** What are some renewable resources?
  **Passage:** […] plants are not mentioned in the passage […]
  **Expected Answer:** Fish, plants

- **Other Domain Specific**
  **Question:** Which position scored the shortest touchdown of the game?
  **Passage:** […] However, Denver continued to pound away as RB Cecil Sapp got a 4-yard TD run, while kicker Jason Elam got a 23-yard field goal. […]
  **Expected Answer:** RB

---

**Intuitive**

We annotate the requirement of intuitive knowledge in order to answer a question common sense knowledge. Opposed to factual knowledge, it is hard to express as a set of facts.

**Question:** Why would Alexander have to declare an heir on his deathbed?

**Passage:** According to Diodorus, Alexander’s companions asked him on his deathbed to whom he bequeathed his kingdom; his laconic reply was "toi kratistoi"—"to the strongest".

**Expected Answer:** So that people know who to follow.
B Detailed annotation results

Here, we report all our annotations in detail, with absolute and relative numbers. Note, that numbers from sub-categories do not necessarily add up to the higher level category, because an example might contain features from the same higher-level category. (for example if an example requires both Bridge and Constraint type of reasoning, it will still count as a single example towards the Operations counter).

Table 9: Detailed linguistic feature results. We calculate percentages relative to the number of examples that were annotated to contain supporting facts.
C Description of selected gold standards

MSMARCO was created by sampling real user queries from the log of a search engine and presenting the search results to experts in order to select relevant passages. Those passages were then shown to crowd workers in order to generate a free-form answer that answers the question or mark if the question is not answerable from the given context. While the released dataset can be used for a plethora of tasks we focus on the MRC aspect where the task is to predict an expected answer (if existent), given a question and ten passages that are extracted from web documents.

HOTPOTQA is a dataset and benchmark that focuses on “multi-hop” reasoning, i.e., information integration from different sources. To that end the authors build a graph from a where nodes represent first paragraphs of Wikipedia articles and edges represent the hyperlinks between them. They present pairs of adjacent articles from that graph or from lists of similar entities to crowd-workers and request them to formulate questions based on the information from both articles and also mark the supporting facts. The benchmark comes in two settings: We focus on the distractor setting, where question and answer are accompanied by a context comprised of the two answer source articles and eight similar articles retrieved by a information retrieval system.

RECORD is automatically generated from news articles, as an attempt to reduce bias introduced by human annotators. The benchmark entries are comprised of an abstractive summary of a news article and a close-style query. The query is generated by sampling from a set of sentences of the full article that share any entity mention with the abstract and by removing that entity. In a final step, the machine-generated examples were presented to crowd workers to remove noisy data. The task is to predict the correct entity given the Cloze-style query and the summary.

MULTIRC features passages from various domains such as news, (children) stories, or textbooks. Those passages are presented to crowd workers that are required to perform the following four tasks: (i) produce questions based multiple sentences from a given paragraph, (ii) ensure that a question cannot be answered from any single sentence, (iii) generate a variable number of correct and incorrect answers and (iv) verify the correctness of produced question and answers. This results in a benchmark where the task is to predict a variable number of correct natural language answers from a variable number of choices, given a paragraph and a question.

NEWSQA is generated from news articles, similarly to RECORD, however by employing a crowd-sourcing pipeline. Question producing crowd workers were asked to formulate questions given headlines and bullet-point summaries. A different set of answer producing crowd workers was tasked to highlight the answer from the article full text or mark a question as unanswerable. A third set of crowd workers selected the best answer per question. The resulting task is, given a question and a news article to predict a span-based answer from the article.

DROP introduces explicit discrete operations to the realm of machine reading comprehension as models are expected to solve simple arithmetic tasks (such as addition, comparison, counting, etc) in order to produce the correct answer. The authors collected passages with a high density of numbers, NFL game summaries and history articles and presented them to crowd workers in order to produce questions and answers that fall in one of the aforementioned categories. A submission was only accepted, if the question was not answered correctly by a pre-trained model that was employed on-line during the annotation process, acting as an adversary. The final task is, given question and a passage to predict an answer, either as a single or multiple spans from the passage or question, generate an integer or a date.
Introduction Example

**Passage 1: Marietta Air Force Station**
Marietta Air Force Station (ADC ID: M-111, NORAD ID: Z-111) is a closed United States Air Force General Surveillance Radar station. It is located 2.1 mi northeast of Smyrna, Georgia. It was closed in 1968.

**Passage 2: Smyrna, Georgia**
Smyrna is a city northwest of the neighborhoods of Atlanta. It is in the inner ring of the Atlanta Metropolitan Area. As of the 2010 census, the city had a population of 51,271. The U.S. Census Bureau estimated the population in 2013 to be 53,438. It is included in the Atlanta-Sandy Springs-Roswell MSA, which is included in the Atlanta-Athens-Clarke-Sandy Springs CSA. Smyrna grew by 28% between the years 2000 and 2012. It is historically one of the fastest growing cities in the State of Georgia, and one of the most densely populated cities in the metro area.

**Passage 3: RAF Warmwell**
RAF Warmwell is a former Royal Air Force station near Warmwell in Dorset, England from 1937 to 1946, located about 5 miles east-southeast of Dorchester; 100 miles southwest of London.

**Passage 4: Camp Pedricktown radar station**
The Camp Pedricktown Air Defense Base was a Cold War Missile Master installation with an Army Air Defense Command Post, and associated search, height finder, and identification friend or foe radars. The station’s radars were subsequently replaced with radars at Gibbsboro Air Force Station 15 miles away. The obsolete Martin AN/FSG-1 Antiaircraft Defense System, a 1957-vintage vacuum tube computer, was removed after command of the defense area was transferred to the command post at Highlands Air Force Station near New York City. The Highlands AFS command post controlled the combined New York-Philadelphia Defense Area.

**Passage 5: 410th Bombardment Squadron**
The 410th Bombardment Squadron is an inactive United States Air Force unit. It was last assigned to the 94th Bombardment Group. It was inactivated at Marietta Air Force Base, Georgia on 20 March 1951.

**Passage 6: RAF Cottesmore**
Royal Air Force Station Cottesmore or more simply RAF Cottesmore is a former Royal Air Force station in Rutland, England, situated between Cottesmore and Market Overton. The station housed all the operational Harrier GR9 squadrons in the Royal Air Force, and No. 122 Expeditionary Air Wing. On 15 December 2009 it was announced that the station would close in 2013 as part of defence spending cuts, along with the retirement of the Harrier GR9 and the disbandment of Joint Force Harrier. However the formal closing ceremony took place on 31 March 2011 with the airfield becoming a satellite to RAF Wittering until March 2012.

**Stramshall**
Stramshall is a village within the civil parish of Uttoxeter Rural in the county of Staffordshire, England. The village is 2.1 miles north of the town of Uttoxeter, 16.3 miles north east of Stafford and 143 miles north west of London. The village lies 0.8 miles north of the A50 that links Warrington to Leicester. The nearest railway station is at Uttoxeter for the Crewe to Derby line. The nearest airport is East Midlands Airport.

**Topsham Air Force Station**
Topsham Air Force Station is a closed United States Air Force station. It is located 2.1 mi north of Brunswick, Maine. It was closed in 1969.

**302d Air Division**
The 302d Air Division is an inactive United States Air Force Division. Its last assignment was with Fourteenth Air Force at Marietta Air Force Base, Georgia, where it was inactivated on 27 June 1949.

**Eldorado Air Force Station**
Eldorado Air Force Station located 35 miles south of San Angelo, Texas was one of the four unique AN/FPS-115 PAVE PAWS, early-warning phased-array radar systems. The 8th Space Warning Squadron, 21st Space Wing, Air Force Space Command operated at Eldorado Air Force Station.

**Question:** What is the 2010 population of the city 2.1 miles southwest of Marietta Air Force Station?
**Expected Answer:** 51,271
