Abstract

Uterine spiral artery remodelling is required for successful human pregnancy; impaired remodelling being associated with pregnancy complications, including late miscarriage, pre-eclampsia and fetal growth restriction. The molecular triggers of remodelling are not known but it is now clear that there are 'trophoblast-independent' and 'trophoblast-dependent' stages. Uterine natural killer (uNK) cells are abundant in decidualised endometrium in early pregnancy; they surround spiral arteries and secrete a range of angiogenic growth factors. We hypothesised that uNK cells mediate initial stages of spiral artery remodelling. uNK cells and extravillous trophoblast cells (EVT) were isolated from early pregnancy decidua and placenta. Chorionic plate arteries from full term placentas and spiral arteries from non-pregnant myometrium were cultured with angiogenic growth factors, or conditioned medium (CM) from uNK cells, EVT or uNK cell/EVT co-cultures. In both vessel models uNK cell-CM induced disruption of vascular smooth muscle cells (VSMCs) and break-down of extracellular matrix components. Angiopoietin (Ang)-1, Ang-2, interferon- γ and vascular endothelial growth factor-C also disrupted VSMC integrity with an Ang-2 inhibitor abrogating the effect of uNK-CM. These results provide compelling evidence that uNK cells contribute to the early stages of spiral artery remodelling; failure of this process could contribute to pregnancy pathology.

Keywords: angiogenic growth factors; proteases; vascular smooth muscle cells

Introduction

Uterine spiral artery (SpA) remodelling is essential for normal human pregnancy; inadequate remodelling of SpA is associated with pregnancy complications including pre-eclampsia, fetal growth restriction, pre-term labour and late miscarriage (1-3). In addition to the immediate morbidity and mortality related to these pregnancy complications there are serious future health consequences for both the mother and offspring of these conditions (4-7). As better, earlier, predictive and diagnostic tools for these pregnancy complications are developed it is imperative that the molecular triggers of SpA remodelling are understood to allow development of effective intervention treatments that may pre-empt the clinical symptoms of these conditions.

During the first 20 weeks of gestation, extravillous trophoblast cells (EVT) migrate from placental chorionic villi, invade uterine decidua and myometrium and remodel decidual and superficial myometrial SpA. The musculo-elastic arterial wall is replaced by an amorphous fibrinoid material containing intramural EVT, creating wide bore channels that lack vasomotor control (2). Although trophoblast appears to be essential to complete the SpA remodelling process, the initial stages, including dilatation, endothelial hyperplasia and vacuolisation of medial smooth muscle, occur in the absence of EVT (8-10). These initial morphological changes have been termed 'trophoblast-independent remodelling' and precede 'trophoblast-associated remodelling' events. **The mechanisms underlying this trophoblast-independent remodelling are unclear, but are likely to be pregnancy specific: in *in vitro* studies, trophoblast cells were not able to invade the wall of myometrial SpA taken at the time of hysterectomy (non-pregnant), but could invade the wall of pregnant myometrial SpA taken at elective Caesarean section at term (11).** Evidence from mouse studies suggests a role for interferon gamma (IFN- γ) secreted by uterine natural killer (uNK) cells in SpA remodelling in the absence of excessive EVT invasion (12-15).

Uterine NK cells are present in high numbers during early human pregnancy and represent up to 70% of the decidual leukocyte population (16). They accumulate in and around SpA in the first trimester of normal pregnancy (10, 17), declining after 20 weeks gestational age (17). Although their function is unknown, recent work has shown that decidua-associated changes in SpA structure are coincident with influx of uNK cells into the arterial wall (10). As well as IFN- γ , uNK cells produce an array of angiogenic growth factors including angiopoietin-1 (Ang-1), Ang-2 and vascular endothelial growth factor-C (VEGF-C) (18, 19), all of which

can modify vascular networks (21, 21). In addition, uNK cells are potent secretors of matrix metalloproteinase-2 (MMP-2) and MMP-9, which have been implicated in decidual vascular remodelling (10, 22).

100 Human SpA consist of a single layer of endothelial cells supported by an internal elastic lamina, and a medial layer of tightly packed vascular smooth muscle cells (VSMCs) with associated extracellular matrix (ECM) (23). Although observational *in situ* studies have suggested a role for uNK cells in trophoblast-independent remodelling, functional studies have not been reported and the underlying mechanisms are not clear. The mechanisms that
105 underpin normal SpA remodelling are not understood and research has focused mainly on the role of trophoblast in this process. We suggest that the uNK cells play an essential early role; defective function of uNK cells in early pregnancy may therefore impact on long term health via pregnancy complications. We hypothesised that for EVT cells to infiltrate and remodel the vessel wall, the medial VSMC layers and their surrounding ECM must be destabilised,
110 and that uNK cells play a role in this process in human pregnancy through secretion of angiogenic growth factors. To test this hypothesis two different *ex vivo* models were used: a high throughput chorionic plate artery model and a more physiological non-pregnant myometrial SpA model. Both models were assessed by immunohistochemistry for disruption of the VSMC morphology and organisation after treatment with different agents of interest.

115

Methods

Sample collection

Placental and decidual samples were obtained at 8-10 and 12-14 weeks gestational age (8-10 weeks n=50; 12-14 weeks n=20) from women undergoing elective surgical termination of pregnancy at the Royal Victoria Infirmary. Chorionic plate artery segments were obtained from normal term placenta (n=50). Myometrial biopsies were obtained from healthy, non-pregnant, pre-menopausal women undergoing hysterectomy at St. Mary's Hospital, Manchester (n=25). Local ethical approval was obtained and all subjects gave informed written consent (NRES committee North East – Sunderland, approval: 07/H0904/74 and Greater Manchester North, approval: 08/H1011/71).

Isolation and culture of CD56+ cells

Uterine NK cell-enriched isolates were prepared by enzymatic disaggregation and positive MidiMACS immunomagnetic selection (MACS, Miltenyi Biotec, Surrey, UK) as described previously (19, 24). Briefly, decidual tissue was finely minced, incubated in DNase/collagenase (both from Sigma Chemical Co., Poole, Dorset, UK), allowed to adhere overnight and subjected to positive immunomagnetic selection (MidiMACS, Miltenyi Biotec., Surrey, UK) with anti-CD56 (Coulter, High Wycombe, UK) to obtain CD56+ cell suspensions. To prepare uNK cell-conditioned medium (uNK-CM, 1×10^5 cells/100 μ l were cultured in a 96 well plate in RPMI1640 complete medium containing 10% fetal bovine serum (FBS), 1% penicillin/streptomycin and 1% amphotericin (all from Sigma Chemical Co.). After 24h the conditioned medium (CM) was removed, centrifuged to eliminate cell debris, and stored at -80°C. Cell purity was tested routinely by immunocytochemical staining of cell smears and was consistently >95%. Viability of uNK cells was assessed after 24h by trypan blue exclusion and was consistently >95%.

Isolation of extravillous trophoblast

EVT were isolated from first trimester placenta as previously described (25, 26). 1×10^6 cells/ml were cultured for 24h in a 24 well plate in DMEM:Ham's F12 supplemented with 10% FBS, 2mM glutamine, 100 units/ml penicillin and 0.1 mg/ml streptomycin (all from Sigma) (DMEM:Ham's F12 complete medium) on growth factor-reduced Matrigel (BD Biosciences, Franklin Lakes, NJ, USA); conditioned medium (EVT-CM) was then harvested. Cell purity was tested by immunostaining for HLA-G and cytokeratin 7 as described

previously (25) and viability was assessed by exclusion of trypan blue; both viability and
150 purity was consistently >95%.

Uterine natural killer and extravillous trophoblast cell co-culture

To prepare uNK cell/EVT co-culture conditioned medium (uNK/EVT-CM) 1×10^6 EVT cells
were cultured in DMEM:Ham's F12 complete medium in a 24 well plate overnight prior to
155 addition of 1×10^6 uNK cells in DMEM:Ham's F12 complete medium to a total volume of
1ml (26). After 24h co-culture the conditioned medium (uNK/EVT-CM) was removed,
centrifuged to eliminate cell debris, and stored at -80°C . Viability of co-cultures was
consistently >95%.

Peripheral blood NK cells

Heparinised venous blood was added to phosphate buffered saline (PBS) in a 1:1 ratio,
subjected to LymphoprepTM (Nycomed Pharma, Oslo, Norway) to obtain a white blood cell
fraction, and then to **MidiMACS positive immunoselection of CD56+ cells as described
above for isolation of uNK cells. 1×10^5 cells/100 μl RPMI complete medium were cultured
165 for 24h and conditioned medium (pbNK-CM) collected as above. Purity and viability was
assessed in the residual cells by immunostaining of cell smears and trypan blue exclusion and
was consistently >95%.**

Cell line culture

170 The SGHPL-4 cell line was a kind gift from Professor Guy Whitley (St George's Medical
School, University of London, UK). This cell line is derived from primary first trimester
extravillous trophoblast cells transfected with the early region of SV40; characterisation has
confirmed an EVT-like phenotype (27, 28). Cells were cultured in Ham's F10 medium
supplemented with 10% FBS, 2mM glutamine, 100 units/ml penicillin and 0.1 mg/ml
175 streptomycin (all from Sigma).

Chorionic plate artery model

Intact chorionic plate artery (CPA) segments (5mm) were dissected from normal term
placenta, cultured in 5% CO_2 at 37°C and incubated at 37°C in 5% CO_2 with: **(A) 20% (v/v)
180 24h uNK-CM (in RPMI1640; 8-10 and 12-14 weeks gestation; n=6 each gestational age
group); (B) 20% (v/v) 24h EVT-CM (in DMEM:Ham's F12; 8-10 and 12-14 weeks
gestation; n=6 each gestational age group); (C) 20% (v/v) 24h uNK/EVT-CM (in**

DMEM:Ham's F12; 8-10 and 12-14 weeks gestation; n=6 each gestational age group); **(D)** 1ng/ml and 10ng/ml VEGF-A (R&D Systems, Abingdon, UK; n=6); **(E)** 1ng/ml and 10ng/ml VEGF-C (R&D Systems; n=6); **(F)** 1ng/ml and 10ng/ml Ang-1 (R&D Systems; n=6); **(G)** 1ng/ml and 10ng/ml Ang-2 (R&D Systems; n=6); **(H)** 1ng/ml and 10ng/ml IFN- γ (R&D Systems; n=6); **(I)** 20% (v/v) uNK-CM (8-10 weeks gestation) + neutralising antibody to Ang-1 (1 μ g/ml; Millipore, Watford, UK; n=5); **(J)** 20% (v/v) uNK-CM (8-10 weeks gestation) + neutralising antibody to Ang-2 (10 μ g/ml; Amgen, Thousand Oaks, CA, USA; n=5); **(K)** 20% (v/v) uNK-CM (8-10 weeks gestation) + neutralising antibody to IFN- γ (2 μ g/ml; R&D Systems; n=5); **(L)** 20% (v/v) uNK-CM (8-10 weeks gestation) + neutralising antibody to VEGF-C (2 μ g/ml; Santa Cruz, Heidelberg, Germany; n=5); **(M)** 20% (v/v) pbNK-CM (in RPMI1640; n=6); **(N)** RPMI medium control (n=6).

The medium was changed every 48h. CPA were harvested after 120h, fixed in 10% neutral buffered formalin and embedded in paraffin wax for immunohistochemistry. 3 μ M serial sections of CPA were immunostained using an avidin biotin peroxidase technique for CD31 (Table 1) to confirm endothelial integrity after culture; CD31-negative vessels were excluded from this study.

Myometrial spiral artery model

SpA were dissected from the superficial and middle layers of the myometrium and cultured in DMEM:F12 complete medium for 72h as described previously (11) in the presence or absence of 20% (v/v) CM or recombinant growth factors, as described above for the chorionic plate artery model. The role of proteases was examined by incubation of SpA with 20% (v/v) uNK-CM with and without a broad spectrum MMP inhibitor (NNGH, 50 μ mol/L; Enzo Life Sciences, Exeter, UK). The ability of uNK-CM to facilitate trophoblast cell invasion was examined by incubation of SpA with uNK-CM for 48h, followed by transfer of SpA into unconditioned (control) medium containing SGHPL-4 trophoblast cells (1x10⁵ cells/ml). To ensure that trophoblast cells were seeded on top of the very small SpA segments, culture plates were coated with a layer of agarose into which small indentations were made. The arterial segments were placed into the indentations, immobilising them within the wells of the culture plate. Trophoblast cells could then be seeded onto the top of the arteries, without them floating away. SpA were cultured for a further 24 or 48h, then were snap frozen and embedded in OCT (Cell Path, Newton, UK).

Immunofluorescence

Transverse frozen sections (10µm) of myometrial artery were fixed (4% (v/v) paraformaldehyde in PBS; 20 min), permeabilised (0.1% (v/v) Triton-X in PBS; 5 min), washed in PBS and immunostained for α smooth muscle actin (α SMA), laminin, fibronectin, collagen IV and elastin. Antibodies were applied for 1h and slides were washed (3 x 5 min; PBS) following each antibody incubation (refer to Table 1 for antibody dilutions). Tissue sections were mounted with Vectashield medium containing propidium iodide and imaged using an Olympus IX70 inverted fluorescence microscope with either a 10x or a 40x oil immersion (Zeiss EC PLAN Neofluar 40X/1.3 oil) objective lens and Axiovision 4.7 image analysis software.

Immunohistochemistry

Paraffin wax-embedded myometrial tissue sections (5µm) and chorionic plate artery sections (3µm) were deparaffinised in xylene and ethanol and subjected to antigen retrieval (Table 1). Endogenous peroxide activity was blocked by incubating slides in 0.5% (v/v) hydrogen peroxide in distilled water for 10 min. After three washes in 0.05M Tris-buffered saline, pH7.6 (TBS), sections were immunostained using a Vector Elite Kit (mouse or rabbit as appropriate; Vector Laboratories, Peterborough, UK) as described previously (19). Primary antibodies (Table 1) were diluted to working concentration in TBS. The reaction was developed by incubation in 0.05% (w/v) DAB and 0.015% (v/v) hydrogen peroxide; sections were then washed in water, lightly counterstained with Mayer's haematoxylin, dehydrated, cleared and mounted in DPX synthetic resin (Raymond Lamb, London, UK).

Morphological assessment of disruption of VSMC organisation

Chorionic plate arteries were immunostained for myosin heavy chain and the morphological appearances of the muscle layers were assessed blinded to the treatment used. Features assessed were the percentage of VSMC rounding, VSMC layer separation and VSMC misalignment using a score of 1=0-10%, 2=10-25%, 3=25-50% and 4=>50%. A VSMC was classified as rounded if it had lost its typical elongated spindled shape. VSMC separation was classified as the appearance of spaces between the different layers of VSMCs. A VSMC was classified as misaligned if it was positioned at a 45 to 90 degree angle to the vessel lumen, rather than being aligned parallel with the circumference of the lumen. Taken together these three parameters provide an indication of the level of VSMC organisation within the vessel model. Isolated myometrial SpA were immunostained for α SMA and counterstained with

propidium iodide. The percentage of misaligned or rounded VSMC, or the percentage area of the arterial wall exhibiting disruption was scored to the nearest 5%. All scoring was blinded and a minimum of 4 sections of each artery were scored to determine a mean value for each vessel.

255

Assessment of inter-observer variability

Thirty CPA tissue sections were assessed independently by two observers (AR and BAI); concordance was defined as within 5% of individual values and was >90% for grading of the morphological assessment of VSMC organisation in CPA.

260

Quantification of ECM immunostaining in CPAs

Digital images of myometrial spiral arteries were captured from each immunostained section using a Nikon Eclipse 80i microscope with a Nikon DS camera system and NIS-Elements software. Using Adobe Photoshop individual chorionic plate arteries were selected using the magnetic lasso tool, copied to a new layer within the image and a stained area identified by eye and selected using the magic wand tool. Other immunopositive areas were then selected using the 'similar' command, with the threshold level set such that all positive areas but no negative areas were selected. The immunopositive areas were then copied into a new layer. The number of pixels in each layer was noted and the positive pixels identified in the immunostained sections were expressed as a percentage of the total number of pixels in the vessel wall for each CPA segment.

265

270

Statistical Analysis

Statistical analyses were performed using the StatView statistical software package (Abacus Concepts, Berkley, CA, USA). Significance was determined using a one-way ANOVA, followed by Fisher's post hoc analysis unless otherwise stated. Differences were considered significant at $P < 0.05$.

275

Results

uNK cell conditioned medium disrupts VSMC organisation

Both uNK-CM and EVT-CM from 8-10 weeks gestational age increased rounding of VSMC in CPAs (Figures 1A, 1C, both $P<0.05$). In addition, uNK-CM enhanced VSMC layer separation (Figures 1B, 1C; $P=0.01$). In contrast, there was no increase in rounding of VSMC after culture with uNK/EVT-CM (Figures 1A, 1C) and no increase in VSMC separation was observed with either EVT-CM or uNK/EVT-CM (Figures 1B, 1C). CPAs cultured with CM from 12-14 weeks gestational age samples showed no alteration in VSMC morphology and organisation. There were no changes in alignment of CPA VSMCs after incubation in any of the conditioned media.

uNK-CM enhanced VSMC misalignment, separation of VSMC layers and rounding of VSMC within non-remodelled myometrial vessels (Figures 1D, 1G, 1J; $P<0.01$, $P<0.001$, $P<0.01$). Furthermore, this effect was specific to uNK cells, as there was no disruption of myometrial artery VSMC architecture after culture in CM from pbNK cells (Figures 1E, 1H, 1K).

uNK cell derived factors disrupt VSMC organisation

Recombinant human Ang-1, Ang-2, and IFN- γ all increased separation of VSMC layers in CPA (Figures 2A, 2D; $P<0.05$, $P<0.01$ and $P=0.05$, respectively), whereas recombinant human Ang-2, IFN- γ and VEGF-C enhanced VSMC rounding (Figures 2B, 2D; $P<0.05$, $P<0.005$ and $P<0.005$, respectively). Activity of these growth factors was only observed at 10ng/ml and not at 1ng/ml. Addition of recombinant TGF- β 1 or VEGF-A did not alter VSMC separation or rounding (data not shown), and none of the recombinant growth factors altered VSMC alignment. Addition of an Ang-2 neutralising antibody (1 μ g/ml) attenuated the uNK-CM induced VSMC separation (Figures 2C, 2D); in contrast, although there was partial abrogation of effect, addition of neutralising antibodies specific for Ang-1 and IFN- γ did not significantly reduce uNK-CM induced VSMC separation. Similarly, neutralising antibodies directed against Ang-1, Ang-2 and VEGF-C partially abrogated uNK-CM induced VSMC rounding, as they were not significantly different from control or uNK-CM levels. None of the neutralising antibodies on their own (in the absence of uNK-CM) had any effect of the three parameters investigated (data not shown).

In the myometrial spiral artery model addition of recombinant human Ang-1 and Ang-2 increased VSMC misalignment (Ang-1 $P<0.01$; Ang-2 $P<0.01$), separation of VSMC layers (Ang-1 $P<0.01$; Ang-2 $P<0.01$) and rounding of VSMCs (Ang-1 $P<0.01$; Ang-2 $P<0.05$) (Figures 3A-3F); these effects were reversed following inclusion of neutralising antibodies. VEGF-C also modestly enhanced VSMC misalignment ($P<0.01$) and rounding of VSMCs ($P<0.01$), but did not induce separation of VSMC layers (Figures 3G-3I). Treatment of SpA with IFN- γ induced rounding of VSMCs ($P<0.05$), but did not alter other parameters of vascular disruption (Figures 3J-3L).

Addition of the pan MMP inhibitor (NNGH) abrogated the effect of uNK-CM on VSMC misalignment, separation of VSMC layers and rounding of VSMCs in the myometrial spiral artery model (Figures 3M-3O; $P<0.05$, $P<0.01$, $P<0.001$, respectively).

uNK cell derived factors initiate ECM remodelling

The types of morphological alterations observed in CPA and myometrial arteries are likely to be associated with changes in the extracellular matrix (ECM) components of the vessels. Therefore, myometrial SpA from non-pregnant women were immunostained for H-caldesmon, fibronectin, collagen IV, elastin and laminin in order to demonstrate ECM components prior to pregnancy and remodelling (Figure 4A). Abundant pericellular expression of collagen IV was observed in the arterial media, along with intense basement membrane staining. Fibronectin expression was observed in the VSMC layers. Intense laminin expression was observed in the endothelial cell basement membrane, with moderate staining in the vessel wall. Elastin expression was detected within the internal elastic lamina, and concentric layers of elastin were observed within the arterial wall, interspersed between layers of VSMC.

To determine whether uNK cell secreted factors altered ECM composition CPA cultured in uNK-CM were assessed for immunostaining and quantity of fibronectin, laminin and collagen IV was quantified using a pixel counting method in Adobe Photoshop. Reduced fibronectin immunostaining was observed in CPA after incubation with uNK-CM (Figure 4B; $P<0.05$). A small but non-significant reduction in laminin expression was noted but there was no change in collagen IV expression (Figure 4B).

Myometrial arteries cultured with uNK-CM were immunostained with antibodies to collagen IV, laminin, fibronectin or elastin and assessed qualitatively (Figures 4C-4F). A marked reduction in immunoreactivity was observed in each case, along with the loss of discrete, organised ECM layers. Furthermore, addition of a broad spectrum matrix metalloproteinase (MMP) inhibitor (NNGH) to the uNK-CM abrogated the effect.

uNK cell derived factors enhance trophoblast-associated vascular remodelling

To determine whether uNK pre-treatment of SpA was sufficient to allow invasion of the vessel by trophoblast cells, SpA were incubated in uNK-CM prior to addition of SGHPL4 extravillous trophoblast-like cells for a further incubation period. The number of invading SGHPL4 cells per tissue section was not altered when arteries were pre-treated with uNK-CM (Figure 5C). Interestingly, pre-treatment of SpA with uNK-CM enhanced trophoblast-associated disruption of VSMC layers and loss of VSMCs (anuclear area) after 24h (Figures 5A, 5B); loss of VSMCs was not observed when SpA were treated with uNK-CM in the absence of trophoblast cells. In addition, this effect was not seen at 48h, implying that priming the SpA with uNK-CM did not confer invading trophoblasts with a significant long term advantage in this model.

Discussion

During the first twenty weeks of gestation, uterine SpAs undergo a progressive wave of remodelling, whereby medial VSMCs are replaced by EVT embedded in a fibrinoid-rich matrix. Despite extensive disruption of arterial wall structure, vascular integrity is maintained and blood flow to the materno-fetal interface is enhanced. The initial stages of remodelling occur in the absence of EVT and include vessel dilatation, endothelial cell vacuolation and VSMC disorganisation (2, 8). Using two *ex vivo* vessel models we demonstrate for the first time in humans that uNK cell derived factors, in particular Ang-2 and proteases, play a significant role in VSMC separation and disorganisation.

Vascular SMC organisation is maintained by cell-cell adhesion and ECM; thus efficient vascular transformation requires both alterations in cell contacts and ECM remodelling. Two *ex vivo* vessel models, chorionic plate arteries and non-pregnant myometrial arteries, were used to investigate the role of angiogenic growth factors and cell culture supernatants on three aspects of VSMC disorganisation; separation, rounding and misalignment. Ang-1, Ang-2, IFN- γ and VEGF-C induced VSMC disorganisation in both vessel types, while VEGF-A and TGF- β 1 had no effect. In chorionic plate arteries, uNK cells derived from pregnancies at 8-10 weeks gestational age also induced VSMC changes, but no change in VSMC morphology was observed using supernatants derived from cells recovered at 12-14 weeks gestation. We have previously demonstrated that higher levels of Ang-1, Ang-2 and VEGF-C are secreted from uNK cells at 8-10, compared with 12-14 weeks gestation (19), which may account for the functional gestational age differences that were observed. In addition to causing alterations in VSMC morphology and organisation, uNK-CM also altered expression levels of several ECM components of the vessel wall. Uterine NK cells are a major source of MMPs within the early pregnancy decidua (10, 22) and inhibition of MMP activity with a pan MMP inhibitor abrogated the effects of uNK-CM on myometrial artery VSMC organisation and ECM components. Incubation of chorionic plate arteries with uNK-CM and neutralising antibodies to Ang-2 partially abrogated the effect of uNK-CM on VSMC disorganisation, while neutralising antibodies to Ang-1, IFN- γ or VEGF-C had less or no effect. These data suggest that uNK cells initiate VSMC separation and ECM degradation in SpA remodeling via the secretion of Ang-2 and MMPs.

Interestingly, pre-treatment of SpA with uNK-derived factors did not significantly increase the number of trophoblast cells invading the vessel wall within the timeframe of our

experiments; however, trophoblast invasion is reportedly focal in nature, with multiple cells colonising small areas of the vascular wall (11), and optimal trophoblast invasion is observed *in vitro* after 72-96 hours (29), making differences in invasion in our pre-treatment model more difficult to detect. Despite this, trophoblast-associated disruption of VSMC layers and loss of VSMCs were enhanced by pre-treatment with uNK-CM, demonstrating that uNK cells can promote trophoblast-mediated remodelling events.

Whilst uNK cells undoubtedly play a role in initiating remodelling events, first trimester EVT also secrete MMPs (30, 31) and angiogenic growth factors (25). Hence, EVT are also equipped to induce vascular destabilisation, which may explain our observation that EVT-CM increased some parameters of VSMC disruption in the chorionic plate artery model. However, EVT-CM did not induce significant destabilisation of myometrial arteries, which may reflect differences in the two vessel models used. Chorionic plate arteries are thicker walled, lack an internal elastic lamina, contain a higher proportion of collagen fibres and their VSMCs are more loosely arranged. This arrangement, where the VSMC are held in less rigid alignment, could leave cells more susceptible to the effects of vasoactive factors and explain why uNK-CM and EVT-CM had more potent effects on chorionic plate arteries than myometrial SpA.

While some differences exist between the two vessel models chosen as they each served a distinct purpose. Chorionic plate arteries are easily obtained from term placenta and are reasonably consistent in size and structure. Therefore they allow a larger number of factors to be tested on the same vessel. The results of the chorionic plate artery model then informed experiments using the more physiologically relevant non-pregnant myometrial arteries which are much smaller in size, technically difficult to obtain as well as it being more difficult to obtain hysterectomy samples from pre-menopausal women. The general consistency in results obtained between the two vessel types confirms the applicability of this approach.

The observation that CM derived from uNK/EVT co-cultures is less bioactive than CM derived from uNK cell cultures alone, highlights the importance of spatio-temporal regulation of different cell types during sequential remodelling events, and might explain why decidual leukocytes initiate vascular disruption prior to the arrival of EVT (10). We have reported that CM from uNK cell/EVT co-cultures contains reduced levels of Ang-1 and VEGF-C compared with expected levels based on secretion by cultures of uNK cells or EVT alone

(26). This suggests that there is a negative feedback loop between uNK cells and EVT that limits the local secretion of angiogenic growth factors, perhaps limits the rate of the spiral artery remodelling process.

435

A role for pbNK cells as mediators of remodelling in several vascular beds has previously been alluded to, although their mechanism of action has never been addressed. PBNK cells have been shown to regulate arteriogenesis in a mouse model of hind limb ischemia (32), and they can promote the development of early-stage atherosclerotic lesions in LDL receptor null mice (33). Our study highlights the unique phenotype of CD56⁺ NK cells isolated from the pregnant uterus, as soluble factors secreted by pbNK cells did not induce remodelling in myometrial SpA.

440

Based on our findings we propose a model whereby uNK cells surround unremodelled SpA in early pregnancy, and secrete Ang-1, Ang-2, VEGF-C, IFN- γ and MMPs to modulate cell-cell and cell-ECM interactions. This allows VSMC to alter their shape and alignment within the arterial wall, disrupting the tightly packed layers. These changes make the arteries more penetrable to EVT, which colonise the wall and cause further disruption, allowing them to efficiently degrade the remaining ECM (31) and replace residual vascular cells. As uNK cells are found predominantly in decidua, they may provide a physiological mechanism for limiting the depth of trophoblast invasion: diffusion of vasoactive factors released by decidual uNK cells may prime superficial myometrial SpA for trophoblast invasion, but failure of these factors to diffuse further into the myometrium may leave the deeper arterial segments refractory to colonisation.

Figure Legends

Figure 1: uNK cell-conditioned medium disrupts VSMC organisation. CPA [A-C] or myometrial SpA [D-L] incubated with unconditioned medium, 20% (v/v) uNK-CM, EVT-CM or uNK/EVT CM and assessed by semi-quantitative morphological assessment for [A] rounding of VSMCs, [B] separation of VSMC layers. [C] Representative photomicrographs of CPA sections immunostained for myosin heavy chain showing rounding of VSMCs and separation of VSMC layers after culture in uNK-CM, EVT-CM or uNK/EVT-CM (8-10 weeks gestational age) (original magnification x400; scale bars = 50µM). Arrows denote rounded cells while high power inserts show separation. Myometrial SpA [D-L] incubated with unconditioned medium, 20% (v/v) uNK-CM, EVT-CM, uNK/EVT CM or pbNK-CM and assessed by semi-quantitative morphological assessment for [D, E] VSMC misalignment, [G, H] separation and [J, K] rounding of VSMCs. [F, I, L] Representative fluorescent immunostaining for αSMA (green) and counterstained with propidium iodide (red) showing [F] VSMC misalignment, [I] separation of VSMC layers and [L] rounding of VSMCs. Each dot represents a different experiment and the bar represents the mean (n=6-10); * $P<0.05$, ** $P<0.01$, *** $P<0.001$; ANOVA with Fishers *post-hoc* test.

Figure 2: uNK cell derived growth factors disrupt VSMC organisation. [A] CPA were incubated with 10ng/ml recombinant human Ang-1, Ang-2, VEGF-C or IFN-γ and the extent of [A] separation of VSMC layers and [B] rounding of VSMCs was assessed semi-quantitatively. [C] CPA were incubated with 20% (v/v) uNK-CM and neutralising antibodies against IFN-γ, Ang-1, Ang-2 and VEGF-C and assessed semiquantitatively for VSMC separation and VSMC rounding. [D] Representative sections of CPA immunostained for myosin heavy chain showing altered VSMC morphology after addition of exogenous Ang-2, IFN-γ and VEGF-C, with partial restoration after addition of neutralising antibody to Ang-2, IFN-γ or VEGF-C to the uNK-CM. Solid boxes show areas of increased rounding while dashed boxes show areas of increased VSMC separation. Scale bars = 100µm. Each dot represents a different experiment and the bar represents the mean (n=6); * $P<0.05$, ** $P<0.01$, *** $P<0.005$; ANOVA with Fishers *post-hoc* test.

Figure 3: uNK cell-derived growth factors disrupt spiral artery architecture. Myometrial SpA were incubated with recombinant human growth factors (10ng/ml) in the presence or absence of neutralising antibodies and assessed semi-quantitatively for VSMC misalignment, separation of VSMC layers and rounding of VSMCs. [A-C] Ang-1, [D-F] Ang-2, [G-I] VEGF-C, [J-L] IFN-γ. [M-O] SpA were incubated with uNK-CM ± NNGH

(50 μ M) and scored for [M] VSMC misalignment, [N] separation of VSMC layers and [O] rounding of VSMCs. Each dot represents a different experiment and the bar represents the median value (n=5-6); * P <0.05, ** P <0.01, *** P <0.001; Kruskal-Wallis.

Figure 4: uNK-CM initiates breakdown of the vascular extracellular matrix. [A] Representative photomicrographs of non-remodelled myometrial SpA from non-pregnant women immunostained for H-caldesmon, collagen IV, fibronectin, laminin, elastin or control IgG. Scale bars = 50 μ M (n=10). [B] CPA cultured with control medium or uNK-CM were immunostained for collagen IV, fibronectin or laminin and immunostaining quantified (n=6); * P <0.05; t -test. [C-F] Representative photomicrographs of SpA incubated with unconditioned medium containing 1.6% (v/v) DMSO (vehicle control), 20% (v/v) uNK-CM or uNK-CM containing the MMP inhibitor NNGH (50 μ M) and immunostained for [C] collagen IV, [D] laminin, [E] elastin and [F] fibronectin (green). Nuclei were counterstained with propidium iodide (red). Scale bars = 50 μ m (n=6).

Figure 5: uNK-CM enhances trophoblast-associated vascular remodelling. SpA were incubated with unconditioned medium (control) or 20% (v/v) uNK-CM for 48h. After transfer to fresh, unconditioned medium, SGHPL4 cells were seeded onto the arteries and were co-cultured for a further 24h or 48h. [A-C] Sections of each artery were stained with propidium iodide and [A, B] an antibody to α SMA or [C] an antibody to cytokeratin-7, and were scored for evidence of [A] loss of VSMCs [B] separation of VSMC layers and [C] trophoblast invasion. Each dot represents a different experiment and the bar represents the median value (n=6); * P <0.05; Kruskal-Wallis. [D-F] Arteries were immunostained with an antibody to α SMA (green) and nuclei were counterstained with propidium iodide (red). Scale bars = 50 μ m.
