THE CLASSIFICATION OF WEIGHTED PROJECTIVE SPACES

ANTHONY BAHRI, MATTHIAS FRANZ, DIETRICH NOTBOHM, AND NIGEL RAY

ABSTRACT. We obtain two classifications of weighted projective spaces; up to homeomorphism and up to homotopy equivalence. We show that the former coincides with Al Amrani’s classification up to isomorphism of algebraic varieties, and deduce the latter by proving that the Mislin genus of any weighted projective space is rigid.

1. Introduction

Weighted projective spaces are the simplest projective toric varieties that exhibit orbifold singularities. They have been extensively investigated by algebraic geometers, but have attracted only fleeting attention from algebraic topologists since Kawasaki’s pioneering work [10], in which he computed their integral cohomology rings. Subsequently, their $K$-theory was determined by Al Amrani [2], and the study of their $KO$-theory was initiated by Nishimura–Yosimura [13].

In toric geometry, weighted projective spaces are classified by their fans. Here, we give two classifications that are fundamental to algebraic topology: up to homeomorphism, and up to homotopy equivalence. We obtain the second as a consequence of the fact that the Mislin genus of a weighted projective space is rigid. Our results are stated below, following summaries of the definitions and notation.

A weight vector $\chi = (\chi_0, \ldots, \chi_n)$ is a finite sequence of positive integers. It gives rise to a weighted action of $S^1$ on $S^{2n+1} \subset \mathbb{C}^{n+1}$,

\begin{equation}
\tau \cdot z = \left( g^{\chi_0} z_0, \ldots, g^{\chi_n} z_n \right)
\end{equation}

for $g \in S^1, z \in S^{2n+1}$. The quotient $S^{2n+1}/S^1(\chi)$ is the weighted projective space $\mathbb{P}(\chi)$. Alternatively, $\mathbb{P}(\chi)$ may be defined as the quotient of $\mathbb{C}^{n+1} \setminus \{0\}$ by the same weighted action of $\mathbb{C}^\times$; this exhibits $\mathbb{P}(\chi)$ as a complex projective variety.

Scaling the weight vector $\chi$ leads to isomorphic weighted projective spaces $\mathbb{P}(\chi)$ and $\mathbb{P}(m\chi)$, for any integer $m \geq 1$. Moreover, if all weights except, say, $\chi_0$ are divisible by some prime $p$, then the map

\begin{equation}
\mathbb{P}(\chi) \to \mathbb{P}(\chi_0, \chi_1/p, \ldots, \chi_n/p), \quad \left[ z_0 : \cdots : z_n \right] \mapsto \left[ z_0^p : z_1 : \cdots : z_n \right]
\end{equation}

is an isomorphism as well, see [5, §5.7]. This leads to the notion of normalized weights: a weight vector $\chi$ is normalized if for any prime $p$ at least two weights in $\chi$ are not divisible by $p$. Any weight vector can be transformed to a unique normalized vector by repeated application of scaling and [1.2]. Consequently, two weighted projective spaces are isomorphic as algebraic varieties and homeomorphic as topological spaces if they have the same normalized weights, up to order. We prove that the converse is also true. In particular, we recover Al Amrani’s classification up to isomorphism of algebraic varieties [1, §8.1].

2010 Mathematics Subject Classification. Primary 55P15; secondary 14M25, 55P60, 57R18.
Theorem 1.1. The following are equivalent for any weight vectors \( \chi \) and \( \chi' \):

1. The normalizations of \( \chi \) and \( \chi' \) are the same, up to order.
2. \( \mathbb{P}(\chi) \) and \( \mathbb{P}(\chi') \) are isomorphic as algebraic varieties.
3. \( \mathbb{P}(\chi) \) and \( \mathbb{P}(\chi') \) are homeomorphic.

For any prime \( p \), the \( p \)-content \( p\chi \) of \( \chi \) is the vector made up of the highest powers of \( p \) dividing the individual weights. For example, \( 2(1, 2, 3, 4) = (1, 2, 1, 4) \). Let \( \chi \) and \( \chi' \) be two normalized weight vectors. It follows from Kawasaki’s result that the cohomology rings \( H^*(\mathbb{P}(\chi); \mathbb{Z}) \) and \( H^*(\mathbb{P}(\chi'); \mathbb{Z}) \) are isomorphic if and only if, for all primes \( p \), the \( p \)-contents \( p\chi \) and \( p\chi' \) are the same up to order. The same phenomenon can be observed in \( K \)-theory and \( KO \)-theory. In fact, no cohomology theory can tell such spaces apart:

Theorem 1.2. Two weighted projective spaces are homotopy equivalent if and only if for all primes \( p \), the \( p \)-contents of their normalized weights are the same, up to order.

The torus \( T = (S^1)^{n+1}/S^1(\chi) \cong (S^1)^n \) and its complexification \( T_\mathbb{C} \) act on \( \mathbb{P}(\chi) \) in a canonical way, and the resulting equivariant homotopy type is a finer invariant. As shown in [3 Thm. 5.1], the equivariant cohomology ring \( H^*_T(\mathbb{P}(\chi); \mathbb{Z}) \) determines the normalized weights up to order.

Let \( p\chi^* \) be the vector obtained from \( p\chi \) by ordering its coordinates as a non-decreasing sequence, and let \( \chi^* \) denote the product of the \( p\chi^* \), taken coordinatewise. For example, \( (1, 2, 3, 4)^* = (1, 1, 2, 12) \). By Theorem 1.2, \( \mathbb{P}(\chi) \) is homotopy equivalent to \( \mathbb{P}(\chi^*) \). The weights in \( \chi^* \) form a divisor chain, in the sense that each weight divides the next. As a consequence, the space \( \mathbb{P}(\chi^*) \) is particularly easy to work with because the differences

\[
\begin{align*}
(1.3) & \quad * = \mathbb{P}(\chi^*), \quad \mathbb{P}(\chi^*_n, \chi^*_{n-1}) \setminus \mathbb{P}(\chi^*_n), \quad \ldots, \quad \mathbb{P}(\chi^*_0, \ldots, \chi^*_1) \setminus \mathbb{P}(\chi^*_1, \ldots, \chi^*_0) \\
(1.4) & \quad * = \mathbb{P}(\chi^*_0) \subset \mathbb{P}(\chi^*_0, \chi^*_1) \subset \cdots \subset \mathbb{P}(\chi^*_0, \ldots, \chi^*_{n-1}) \subset \mathbb{P}(\chi^*_0, \ldots, \chi^*_n)
\end{align*}
\]

form a cell decomposition of \( \mathbb{P}(\chi^*) \) (see Remark 3.3 below), and displays \( \mathbb{P}(\chi^*) \) as an iterated Thom space [4 Cor. 3.8].

The Mislin genus of a weighted projective space \( \mathbb{P}(\chi) \) is the set of all homotopy classes of simply connected CW complexes \( Y \) of finite type such that for all primes \( p \) the \( p \)-localizations of \( Y \) and \( \mathbb{P}(\chi) \) are homotopy equivalent. The Mislin genus of a space is rigid if it contains only the class of the space itself.

Theorem 1.3. The Mislin genus of any weighted projective space is rigid.

For \( \mathbb{C}P^n \), this has been established by McGibbon [11 Thm. 4.2 (ii)].

In Section 2 we review Kawasaki’s results on which our work is based. Theorem 1.1 is proved in Section 3 and Theorems 1.2 and 1.3 in Section 5; necessary conditions for the rigidity of the Mislin genus are established in Section 4.

2. Kawasaki’s results

From now on, \( \chi = (\chi_0, \ldots, \chi_n) \) always denotes a normalized a weight vector, and cohomology is taken with integer coefficients unless otherwise stated. In order to make Kawasaki’s description of \( H^*(\mathbb{P}(\chi)) \) explicit, it is convenient to recall his
notation \((r_0(\chi; p), \ldots, r_n(\chi; p))\) for the non-decreasing weight vector \(p\chi^*\); given any \(0 \leq i \leq n\), we then set
\[
(2.1) \quad l_i = l_i(\chi) = \prod_{p \text{ prime}} r_{n-i+1}(\chi; p) \cdots r_n(\chi; p).
\]

We also consider the map
\[
(2.2) \quad \varphi = \varphi_\chi : \mathbb{C}P^n \to \mathbb{P}(\chi), \quad [z_0 : \cdots : z_n] \mapsto [z_0^{\chi_0} : \cdots : z_n^{\chi_n}].
\]

**Theorem 2.1** ([10, Thm. 1]). Additively, \(H^*(\mathbb{P}(\chi)) \cong H^*(\mathbb{C}P^n)\). Furthermore, there exist generators \(\xi_i \in H^{2i}(\mathbb{P}(\chi))\) and \(\eta \in H^2(\mathbb{C}P^n)\) such that \(\varphi^*(\xi_i) = l_i\eta^i\) for \(0 \leq i \leq n\); the multiplicative structure is specified by
\[
\xi_i\xi_j = \frac{l_{i+j}}{l_i} \xi_{i+j}
\]
in \(H^{2(i+j)}(\mathbb{P}(\chi))\), for \(0 \leq i + j \leq n\).

**Remarks 2.2.** Kawasaki’s proof of Theorem 2.1 shows that the integral homology groups \(H_* (\mathbb{P}(\chi))\) are finitely generated and torsion-free, and therefore isomorphic to \(\text{Hom}(H^*(\mathbb{P}(\chi)), \mathbb{Z})\) by the Universal Coefficient Theorem.

Moreover, [5, Sec. 3.2] and [9, Cor. 7.2] confirm that \(P(\chi)\) is a simply connected finite CW complex, for every choice of \(\chi\).

Kawasaki also determined the cohomology of the generalized lens space \(L(k; \chi) = S^{2n+1}/\mathbb{Z}_k(\chi)\), where in this case \(\chi\) describes the weights of the \(k\)-th roots of unity.

The answer depends on the augmented weight vector \((\chi, k) = (\chi_0, \ldots, \chi_n, k)\).

**Theorem 2.3** ([10, Thm. 2]). The non-zero cohomology groups of \(L = L(k; \chi)\) are \(H^0(L) \cong H^{2n+1}(L) \cong \mathbb{Z}\) and \(H^{2i}(L) \cong \mathbb{Z}_q\) for \(1 \leq i \leq n\), where \(q = l_i(\chi, k) / l_i(\chi)\).

3. **Classification up to homeomorphism**

Consider a point \(z \in \mathbb{P}(\chi)\). Let \(I\) and \(J\) be the subsets of \(\{0, \ldots, n\}\) corresponding to the zero and non-zero homogeneous coordinates of \(z\), respectively, and let \(q = \gcd\{\chi_i : i \in J\}\). Also, let \(U_I = \{[z_0 : \cdots : z_n] : z_i \neq 0 \text{ for } i \notin I\}\), and write \(\chi_I \in \mathbb{Z}^I\) for the weights indexed by \(I\).

**Lemma 3.1** (cf. [5, §5.15]). There is an isomorphism of algebraic varieties
\[
U_I \cong (\mathbb{C}^\infty)^{|J| - 1} \times \mathbb{C}^I / \mathbb{Z}_q(\chi_I),
\]
sending \(z\) to a point of the form \((\bar{z}, 0)\).

Observe that \(\mathbb{C}^I / \mathbb{Z}_q(\chi_I)\) is the unbounded cone over \(L(q; \chi_I)\).

**Proof.** The weight vector \(\chi_I\) determines a morphism \(\mathbb{C}^\infty \to (\mathbb{C}^\infty)^I\) with kernel \(\mathbb{Z}_q\). Let \(T'\) be its image and \(T'' \cong (\mathbb{C}^\infty)^{|I| - 1}\) a torus complement. Then
\[
U_I = ((\mathbb{C}^\infty)^J \times \mathbb{C}^I) / \mathbb{C}^\infty(\chi) = (T'' \times T' \times \mathbb{C}^I) / \mathbb{C}^\infty(\chi) = T'' \times \mathbb{C}^I / \mathbb{Z}_q(\chi_I). \quad \square
\]

**Remark 3.2.** If \(\chi_0 = 1\) and \(z = [1 : 0 : \cdots : 0]\), then \(U_I \cong \mathbb{C}^n\). If the weights form a divisor chain, we have \(\mathbb{P}(\chi) \setminus U_I = \mathbb{P}(\chi_1, \ldots, \chi_n) = \mathbb{P}(1: \chi_2/\chi_1, \ldots, \chi_n/\chi_1)\); hence we obtain an inductive decomposition of \(\mathbb{P}(\chi)\) into \(n + 1\) cells \(*, \mathbb{C}, \mathbb{C}^2, \ldots, \mathbb{C}^n\).

**Lemma 3.3.** There is an isomorphism \(H^{2n-1}(\mathbb{P}(\chi), \mathbb{P}(\chi) \setminus \{z\}) \cong \mathbb{Z}_q\).
Proof. Set $X = (\mathbb{C}^\times)^{|I|-1}$, $Y = \mathbb{C}^I/\mathbb{Z}_q(\chi_I)$ and $m = |I| - 1$. Note that $X$ is a manifold of dimension $2(n - m - 1)$, so that $H^*(X, X \setminus \{z\})$ is isomorphic to $\mathbb{Z}$ in dimension $2(n - m - 1)$ and zero otherwise. Excision, Lemma 3.1 and the Künneth formula for relative cohomology therefore imply

\[ H^*(\mathbb{P}(\chi), \mathbb{P}(\chi) \setminus \{z\}) \cong H^*(U_I, U_I \setminus \{z\}) \]
\[ \cong H^*(X \times Y, (X \setminus \{z\}) \times Y \cup X \times (Y \setminus \{0\})) \]
\[ \cong H^*(X, X \setminus \{z\}) \otimes H^*(Y, Y \setminus \{0\}), \]

because $H^*(X, X \setminus \{z\})$ is free. In particular,

\[ H^{2n-1}(\mathbb{P}(\chi), \mathbb{P}(\chi) \setminus \{z\}) \cong H^{2m+1}(Y, Y \setminus \{0\}) \cong \tilde{H}^{2m}(L(q; \chi_I)). \]

If $m = 0$, then $q = 1$ because $\chi$ is normalized, and the claim holds. Otherwise, Theorem 2.3 gives $H^{2m}(L(q; \chi_I)) \cong \mathbb{Z}_{q'}$, where the $p$-content of $q'$ is given by

\[ p\text{-content of } \frac{l_m(\chi_I, q)}{l_m(\chi_I)} = \prod_{i=1}^{m} \frac{r_{m+2-1}(\chi_I; q; p)}{r_{m+1-1}(\chi_I; p)}. \]

We have to show $q' = q$, which means that $q'$ and $q$ have the same $p$-content for all $p$. This is clearly true if $q$ is not divisible by $p$. Otherwise, $\chi_I$ inherits from the normalized weight vector $\chi$ two weights not divisible by $p$. (Recall that $q$ is the gcd of the weights appearing in $\chi$, but not in $\chi_I$.) Hence, $r_1(\chi; p) = 1$, and the numerator of (3.1) differs from the denominator by the $p$-content of $q$. This finishes the proof. \hfill \Box

Proof of Theorem 1.1. By the remarks preceding the theorem, we only have to prove the implication $\boxed{3} \Rightarrow \boxed{1}$. In order to do so, we show how to read off the normalized weights from topological invariants of a weighted projective space $\mathbb{P}(\chi)$. For $z \in \mathbb{P}(\chi)$, let $q'(z)$ be the order of the finite group $H^{2n-1}(\mathbb{P}(\chi), \mathbb{P}(\chi) \setminus \{z\})$. Lemma 3.3 implies that for all $d \geq 1$ the space

\[ X(d) = \{ z \in \mathbb{P}(\chi) : d \mid q'(z) \} \]

is again a weighted projective space or empty. In fact,

\[ X(d) = \{ [z_0 : \cdots : z_n] \in \mathbb{P}(\chi) : z_i = 0 \text{ if } d \nmid \chi_i \} \]

because $d$ divides $q'(z) = q$ if and only if it divides $\chi_i$ for all $i$ such that $z_i \neq 0$. For each $d$, the dimension of $X(d)$ (which equals the degree of the highest non-vanishing cohomology group) therefore tells us the number of weights divisible by $d$. This determines the normalized weights completely up to order. \hfill \Box

4. The Mislin Genus

This section relies heavily on the theory of localization and homotopy pullbacks. We refer readers to [7], especially Chapter II, and to [14, Chap. 7], for background information.

Throughout the section, $X$, $Y$, and $Z$ denote simply connected CW complexes. A map $f : X \to Y$ is therefore a homotopy equivalence (written $X \simeq Y$) if and only if it induces an isomorphism $H_*(f)$ of integral homology; in this case, $f^{-1}$ denotes a homotopy inverse for $f$.

Given any set $\mathcal{P}$ of primes, the algebraic localization of $Z$ is denoted by $Z_\mathcal{P}$, and the homotopy theoretic localization of $X$ by $X_\mathcal{P}$; the latter is also a CW complex.
Every $X$ admits a localization map $l_P: X \to X_P$, which induces an isomorphism $H_*(l_P; \mathbb{Z}_P)$, and every $f$ admits a localization $f_P: X_P \to Y_P$, for which the square

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow l_P & & \downarrow l_P \\
X_P & \longrightarrow & Y_P
\end{array}
$$

is homotopy commutative. Any map $g: X_P \to Y_P$ of localized spaces is a homotopy equivalence if and only if it induces an isomorphism $H_*(g; \mathbb{Z}_P)$.

If $P$ is empty, then the localization map $l_{\emptyset}$ is rationalization, and is denoted by $l_0: X \to X_0$; likewise, $f_0$ is denoted by $f_0: X_0 \to Y_0$. If $P$ consists of a single prime $p$, then the localization map $l_{\{p\}}$ is abbreviated to $l_p: X \to X_p$, and $f_{\{p\}}$ is abbreviated to $f_p: X_p \to Y_p$. If $P$ contains all primes, then $l_P$ is a homotopy equivalence.

The homotopy pullback of a diagram $X \to Z \leftarrow Y$ may be constructed by replacing either map with a fibration, and pulling it back along the other in the standard fashion. The resulting square is unique up to equivalence of diagrams in the homotopy category $[14, \S 7.3]$; in particular, the homotopy pullback is well-defined up to homotopy equivalence.

For any set of primes $P$, the rationalization of $X_P$ is homotopy equivalent to $X_0$, so the rationalization map may be expressed as $l_0: X_P \to X_0$. If $P$ and $Q$ are disjoint, then the homotopy pullback of

$$
\begin{array}{ccc}
X_Q & \longrightarrow & X_0 \\
\downarrow l_0 & & \downarrow l_0 \\
X_P & \longrightarrow & X_P
\end{array}
$$

is $X_{P \cup Q}$ (see $[12$, Prop. 2.9.3$]$ or $[7$, proof of Thm. 7.13$]$).

**Lemma 4.1.** Given two disjoint sets $P$ and $Q$ of primes, let $f: Y_P \to Z_P$ and $g: Y_Q \to Z_Q$ be homotopy equivalences, and define $h = f_0g_0^{-1}$; then $Y_{P \cup Q}$ is the homotopy pullback of the diagram

$$
\begin{array}{ccc}
Z_Q & \longrightarrow & Z_0 \\
\downarrow h_0 & & \downarrow l_0 \\
Z_P & \longrightarrow & Z_P
\end{array}
$$

If also there exist homotopy equivalences $d: Z_P \to Z_P$ and $e: Z_Q \to Z_Q$ such that $h \simeq d_0e_0^{-1}$, then $Y_{P \cup Q}$ and $Z_{P \cup Q}$ are homotopy equivalent.

**Proof.** The vertical maps in the homotopy commutative ladder

$$
\begin{array}{ccc}
Y_Q & \longrightarrow & Y_0 \\
\downarrow g & & \downarrow f_0 \\
Z_Q & \longrightarrow & Z_0 \\
\downarrow h_0 & & \downarrow l_0 \\
Z_P & \longrightarrow & Z_P
\end{array}
$$

are homotopy equivalences, and the homotopy pullback of the upper row is $Y_{P \cup Q}$, by analogy with $[14]$. So the ladder induces a homotopy equivalence of homotopy pullbacks following $[14, \S 7.3]$, and the first claim follows.

Substituting $Y = Z$, $f = d$ and $g = e$ into $[14]$ creates an upper row with homotopy pullback $Z_{P \cup Q}$. The second claim is then immediate.

The following proposition gives criteria for ensuring that the genus of a finite CW complex is rigid.

**Proposition 4.2.** Let $Z$ be a simply connected finite CW complex satisfying
(i) for any space $Y$ in the Mislin genus of $Z$, there exists a rational homotopy equivalence $k: Y \to Z$, and
(ii) for any disjoint sets $\mathcal{P}$ and $\mathcal{Q}$ of primes, and any rational homotopy equivalence $h: Z_0 \to Z_0$, there exist homotopy equivalences $d: Z_\mathcal{P} \to Z_\mathcal{P}$ and $e: Z_\mathcal{Q} \to Z_\mathcal{Q}$ such that $h \simeq d_0 e_0^{-1}$:

then the genus of $Z$ is rigid.

Proof. Let $Y$ belong to the Mislin genus of $Z$. It follows from [7, p. 105] that there is an isomorphism $H_*(Y; \mathbb{Z}) \cong H_*(Z; \mathbb{Z})$ of graded abelian groups. Since $H_*(k; \mathbb{Q})$ is an isomorphism, there exists a maximal set $\mathcal{Q}$ of primes for which $H_*(k_\mathcal{Q})$ is also an isomorphism. Since $H_*(Y; \mathbb{Z})$ and $H_*(Z; \mathbb{Z})$ are finitely generated in each dimension (and vanish in large dimensions), its complement $\mathcal{P}$ is finite. If $\mathcal{P}$ is non-empty, write its elements as $p_1, \ldots, p_s$ and define $\mathcal{Q}_i = \mathcal{Q} \cup \{p_1, \ldots, p_i\}$; otherwise, take $\mathcal{Q}_0 = \mathcal{Q}$. Since $\mathcal{Q}_i$ contains all primes, it suffices to show that $Y_{\mathcal{Q}_i} \simeq Z_{\mathcal{Q}_i}$.

In fact we prove that $Y_{\mathcal{Q}_i} \simeq Z_{\mathcal{Q}_i}$ for every $0 \leq i \leq s$, using induction on $i$. The base case is $i = 0$; it holds because $H_*(k)$ is an isomorphism when $\mathcal{P} = \emptyset$, so $k$ is a homotopy equivalence. Now assume that $g: Y_{\mathcal{Q}_i} \to Z_{\mathcal{Q}_i}$ is a homotopy equivalence, and write $p = p_{i+1}$. By choice of $Y$, there is a homotopy equivalence $f: Y_{\mathcal{P}} \to Z_{\mathcal{P}}$, so we may apply the first claim of Lemma 4.1. This identifies $Y_{\mathcal{Q}_{i+1}}$ as the homotopy pullback of

$$Z_{\mathcal{Q}_i} \xrightarrow{h_0} Z_0 \xleftarrow{t_0} Z_p,$$

where $h$ is the homotopy equivalence $f_0 h_0^{-1}: Z_0 \to Z_0$. By assumption, there exist homotopy equivalences $d: Z_{\mathcal{P}} \to Z_{\mathcal{P}}$ and $e: Z_{\mathcal{Q}_i} \to Z_{\mathcal{Q}_i}$ such that $h \simeq d_0 e_0^{-1}$. The second claim of Lemma 4.1 then confirms that $Y_{\mathcal{Q}_{i+1}} \simeq Z_{\mathcal{Q}_{i+1}}$, and completes the inductive step. \qed

5. Classification up to homotopy equivalence

Finally, we return to the case of weighted projective space.

In Theorem 2.1 we selected a generator $\xi_i$ for $H^2(\mathbb{P}(\chi)) \cong \mathbb{Z}$. Given any set of primes $\mathcal{P}$, its localization in $H^2(\mathbb{P}(\chi)_p; \mathbb{Z}) \cong \mathbb{Z}_p$ must also be a generator. We therefore define the degree $\deg(h)$ of any self-map $h$ of $\mathbb{P}(\chi)_p$ to be the $\mathcal{P}$-local integer satisfying $H^*(h; \mathbb{Z}_p)(\xi_1) = \deg(h) \xi_1$; this determines a multiplicative function

$$\deg: [\mathbb{P}(\chi)_p, \mathbb{P}(\chi)_p] \to \mathbb{Z}_p.$$  

Remark 2.2 shows that any such $h$ is a homotopy equivalence if and only if $H^*(h; \mathbb{Z}_p)$ is an isomorphism.

Proposition 5.1.

1. A self-map of $\mathbb{P}(\chi)_p$ is a homotopy equivalence if and only if its degree is a unit in $\mathbb{Z}_p$.
2. The degree function $\deg$ is surjective.
3. If $\mathcal{P}$ contains no divisor of any $\chi_j$, then the degree function is a bijection.

Proof. Since $\deg$ is multiplicative and the degree of the identity map is 1, it maps homotopy equivalences to units. Let $h$ be any self-map of $\mathbb{P}(\chi)_p$, and assume that $h$ has degree $a$. By Theorem 2.1, $H^*(h; \mathbb{Z}_p)$ induces multiplication by $a^k$ on $H^k(\mathbb{P}(\chi)_p; \mathbb{Z}) \cong \mathbb{Z}_p$, for every $1 \leq k \leq n$. If $a$ is a unit, then $H^*(h; \mathbb{Z}_p)$ is an isomorphism, so $h$ is a homotopy equivalence. Thus 1 holds.
Fix a positive integer \( a \), and define the self-map \( m_a : \mathbb{P}(\chi) \to \mathbb{P}(\chi) \) by raising each homogeneous coordinate to the power \( a \); in particular, write \( m_a' : \mathbb{CP}^n \to \mathbb{CP}^n \) for the standard case. Thus \( m_a \) and \( m_a' \) commute with the map \( \varphi \) of \( \mathbb{CP}^n \), leading to the commutative diagram

\[
\begin{array}{ccc}
H^*(\mathbb{P}(\chi)) & \xrightarrow{H^*(\varphi)} & H^*(\mathbb{CP}^n) \\
\downarrow H^*(m_a) & & \downarrow H^*(m_a') \\
H^*(\mathbb{P}(\chi)) & \xrightarrow{H^*(\varphi)} & H^*(\mathbb{CP}^n)
\end{array}
\]

Since \( H^2(m_a') \) is multiplication by \( a \), it follows that \( \deg(m_a) = a \). But every element \( c \in \mathbb{Z}_P \) may be written as a quotient \( c = b/a \) of integers, where \( a \) is a positive unit in \( \mathbb{Z}_P \). Then \( \mathbb{CP}^n \) follows from \( \mathbb{CP}^n \), combined with the observations that complex conjugation on a single coordinate has degree \(-1\), and constant self-maps have degree \(0\).

If \( P \) contains no divisor of any weight, then \( \varphi_P : \mathbb{CP}_P^n \to \mathbb{P}(\chi)_P \) is a homotopy equivalence by Theorem 2.1. To prove \( \mathbb{CP}^n \), it therefore suffices to consider maps \( h_1, h_2 : \mathbb{CP}_P^n \to \mathbb{CP}_P^n \) of equal degree; in other words, we may restrict attention to the special case \( \mathbb{CP}^n \). Since \( \mathbb{CP}^n \) is an Eilenberg–MacLane space \( K(\mathbb{Z}_P, 2) \), the compositions of \( ip : \mathbb{CP}_P^n \to \mathbb{CP}^n \) with \( h_1 \) and \( h_2 \) are homotopic. Moreover, \( \mathbb{CP}_P^n \) is \( 2n \)-dimensional and its image is the \((2n+1)\)-skeleton of \( \mathbb{CP}^n \), so the homotopy corestricts to a homotopy \( h_1 \simeq h_2 \). Thus \( \deg \) is injective, and \( \mathbb{CP}^n \) follows.

The special case \( \mathbb{CP}^n \) of part \( \mathbb{CP}^n \) is well-known \[11\] Thm. 2.2], but is stated there without proof.

To complete the proof of Theorem 1.3, it remains only to show that the criteria of Proposition 4.2 apply to \( \mathbb{P}(\chi) \).

**Proof of Theorem 1.3.** Let \( Y \) be an element of the Mislin genus of \( \mathbb{P}(\chi) \). Since \( H_*(Y) \cong H_*(\mathbb{P}(\chi)) \) as graded abelian groups, \( Y \) is homotopy equivalent to a CW complex of dimension \( 2n \), by \[3\] Prop. 4C.1. Furthermore, \( H^*(\mathbb{P}(\chi); \mathbb{Q}) \) is multiplicatively generated by a single element of degree \( 2 \), so any of the homotopy equivalences \( Y_p \simeq \mathbb{P}(\chi)_p \) induces the corresponding structure on \( H^*(Y; \mathbb{Q}) \). A multiplicative generator \( \gamma \) may be chosen to be integral in \( H^2(Y; \mathbb{Q}) \), because the Universal Coefficient Theorem confirms that \( H^2(Y; \mathbb{Z}) \cong \mathbb{Z} \). Also, \( \gamma \) is represented by a map \( j : Y \to \mathbb{CP}^n \cong K(\mathbb{Z}, 2) \), for which \( H^2(j; \mathbb{Z}) \) is an isomorphism. Up to homotopy, \( j \) factors through \( \mathbb{CP}^n \subset \mathbb{CP}^\infty \), so its corestriction \( j' : Y \to \mathbb{CP}^n \) is a rational homotopy equivalence. Since \( \varphi : \mathbb{CP}^n \to \mathbb{P}(\chi) \) is a rational homotopy equivalence by Theorem 2.1, the same holds for the composition \( \varphi j' : Y \to \mathbb{P}(\chi) \). Criterion (i) of Proposition 4.2 is therefore satisfied by \( k = \varphi j' \).

Now let \( h : \mathbb{P}(\chi)_0 \to \mathbb{P}(\chi)_0 \) be a homotopy equivalence, let \( \deg(h) = \pm a/b \) where \( a, b \in \mathbb{N} \), and let \( P \) and \( Q \) be two disjoint sets of primes. Write \( a = a'a'' \) and \( b = b'b'' \), where \( a', b' \) are divisible only by primes not contained in \( P \), and \( a'', b'' \) are divisible only by primes contained in \( P \). Then \( a'/b' \in \mathbb{Z}_P \) and \( b''/a'' \in \mathbb{Z}_Q \) are units. So Proposition 5.1(2) guarantees the existence of homotopy equivalences \( d : \mathbb{P}(\chi)_P \to \mathbb{P}(\chi)_P \) and \( e : \mathbb{P}(\chi)_Q \to \mathbb{P}(\chi)_Q \) of degrees \( \pm a'/b' \) and \( b''/a'' \) respectively, and \( h \simeq d_0 e_0^{-1} \) by Proposition 5.1(4). Criterion (ii) of Proposition 4.2 is therefore satisfied, as required. \[ \square \]
Proof of Theorem 1.2. If \( \chi \) and \( \chi' \) have the same \( p \)-content up to order, then some permutation of homogeneous coordinates defines a homeomorphism \( \mathbb{P}(\chi) \cong \mathbb{P}(\chi') \) for each prime \( p \). This homeomorphism may be localized at \( p \).

Now consider the map

\[
g: \mathbb{P}(\chi) \to \mathbb{P}(\chi), \quad [z_0 : \cdots : z_n] \mapsto [z_0^{\alpha(0)} : \cdots : z_n^{\alpha(n)}],
\]

where \( \alpha(j) = \chi_j / p \chi_j \) for \( 0 \leq j \leq n \). Theorem 2.1 implies that \( H^*(g; \mathbb{Z}_p) \) is an isomorphism, and Remarks 2.2 confirm that \( g_p \) is a homotopy equivalence. So \( g^{-1}_p \) and \( g'_p \) determine a chain of maps

\[
\mathbb{P}(\chi)_p \cong \mathbb{P}(\chi')_p \cong \mathbb{P}(\chi')_p \cong \mathbb{P}(\chi')_p
\]

for any prime \( p \), and the result follows from Theorem 1.3. \( \square \)

Acknowledgements. The authors are particularly grateful to the referee, whose suggestions led to several improvements in the structure and exposition of this work. A. B. was supported in part by a Rider University Summer Research Fellowship and Grant #210386 from the Simons Foundation, and M. F. by an NSERC Discovery Grant.
